Interstate Operations Study: Fargo-Moorhead Metropolitan Area

2025 Simulation Results

Technical Memorandum IV

October 2009

Prepared for:
Fargo-Moorhead Council of Governments
(Metro COG)

Prepared by:
Advanced Traffic Analysis Center
Upper Great Plains Transportation Institute
North Dakota State University
Fargo, North Dakota

EXECUTIVE SUMMARY

This document provides the simulation results for the 2025 planning horizon of the Fargo-Moorhead Interstate Operations Study. Previous material focused on the simulation development process (Technical Memorandum I), the calibration process and the simulation results of the 2008 base cases (Technical Memorandum II), and the results of the 2015 simulation scenarios (Technical Memorandum III). Major sections of this document include the network modifications, traffic demand, and simulation results for the 2025 peak-hour scenarios. Based on the simulation output, the proposed near-term (by 2015) and long-term improvements (by 2025) reduced congestion at several areas within the study area during the peak periods.

The simulation study area includes all of the freeway interchanges of I-29 and I-94 within the cities of Fargo, ND; West Fargo, ND; and Moorhead, MN. Ten interchanges were modeled with local roadways along the 15-mile portion of I-94 and 7 interchanges along the 9-mile portion of I-29. The simulation analysis was performed using PTV AG's VISSIM traffic simulation program.

The freeway mainline densities that experienced congestion were generally along I-94 between I-29 and 20th St. (Moorhead, MN). The highest density values for the 2025 AM scenario were along the westbound sections of I-94 from 20th St. (Moorhead, MN) to I-29, which exhibited densities between 29 pc/mi/ln to 35 pc/mi/ln (LOS D-E). For the 2025 PM scenario, the highest density values were along the eastbound sections of I-94 from 25th St. (Fargo, ND) to 20th St. (Moorhead, MN) with densities ranging from 31 pc/mi/ln to 34 pc/mi/ln (LOS D).

The I-29 & I-94 Interchange experienced a significant number of vehicles during the peak periods; however, significant congestion did not develop at any of the ramps. Modifying the tri-level ramp and merge area (2025 network) alleviated the congestion that developed during the PM peak period. During both the 2008 PM and the 2015 PM scenarios, the merge area experienced significant congestion, producing maximum queue lengths of 2,027 ft and 5,506 ft, respectively. Incorporating a two lane tri-level ramp and auxiliary lane between I-29 and 25th St. (Fargo, ND) significantly improved traffic flow through the merge area.

The geometric improvements that are proposed by 2025 at several freeway interchanges significantly reduced congestion that was evident in previous scenarios. For both the 2025 AM and 2025 PM scenarios, the addition of the I-94 and 9th St. Interchange (2015 network) reduced congestion at the I-94 and Sheyenne St. Interchange and I-94 and 45th St. Interchange. The most influential improvement to this scenario (2025 network) related to the modified design of the I-94 & 8th St. (TH 75) Interchange, which significantly reduced congestion at the north ramp during the 2025 AM scenario and the south ramp during the 2025 PM scenario.

A few off-ramp and on-ramp locations showed signs of periodic congestion during the peak periods. Although no quantitative data were collected at these locations, the westbound traffic accessing the northeast loop of the I-29 and I-94 Interchange (AM peak), the eastbound on-ramp at 25th St. (PM peak), and the southbound on-ramp at Main Ave. (PM peak) experienced some congestion when observing the simulation animation.

To illustrate the effects of not incorporating the proposed 2025 network improvements, two additional scenarios were analyzed using the 2025 traffic on the 2015 network (2025/2015). During the AM and PM periods, significant congestion existed at the I-94 and 8th St. (TH 75) interchange. In addition, the PM peak period experienced significant congestion at the tri-level merge area. During the AM peak, the 2025/2015 scenario produced 47% more delay time compared to the 2025 network, while the PM peak using the 2025/2015 scenario produced 404% more delay compared to the 2025 PM scenario.

OVERVIEW

This document provides the simulation results for the 2025 planning horizon of the Fargo-Moorhead Interstate Operations Study (F-M IOS). Previous material focused on the simulation development process (Technical Memorandum I), the calibration process and the simulation results of the 2008 base cases (Technical Memorandum II), and the results of the 2015 simulation scenarios (Technical Memorandum III). Major sections of this document include the network modifications, traffic demand, and simulation output for the 2025 peak-hour scenarios.

2025 SIMULATION STUDY AREA

The simulation study area includes all of the freeway interchanges of Interstate 29 (I-29) and Interstate 94 (I-94) within the cities of Fargo, ND; West Fargo, ND; and Moorhead, MN (Figure 1). Ten interchanges will be modeled with local roadways along the 15-mile portion of I-94 and 7 interchanges along the 9-mile portion of I-29. The simulation analysis, which uses PTV AG's VISSIM 5.1, will provide numerical data and animation that will provide guidance on locations suffering from capacity deficiencies resulting from continued growth within the metropolitan area.

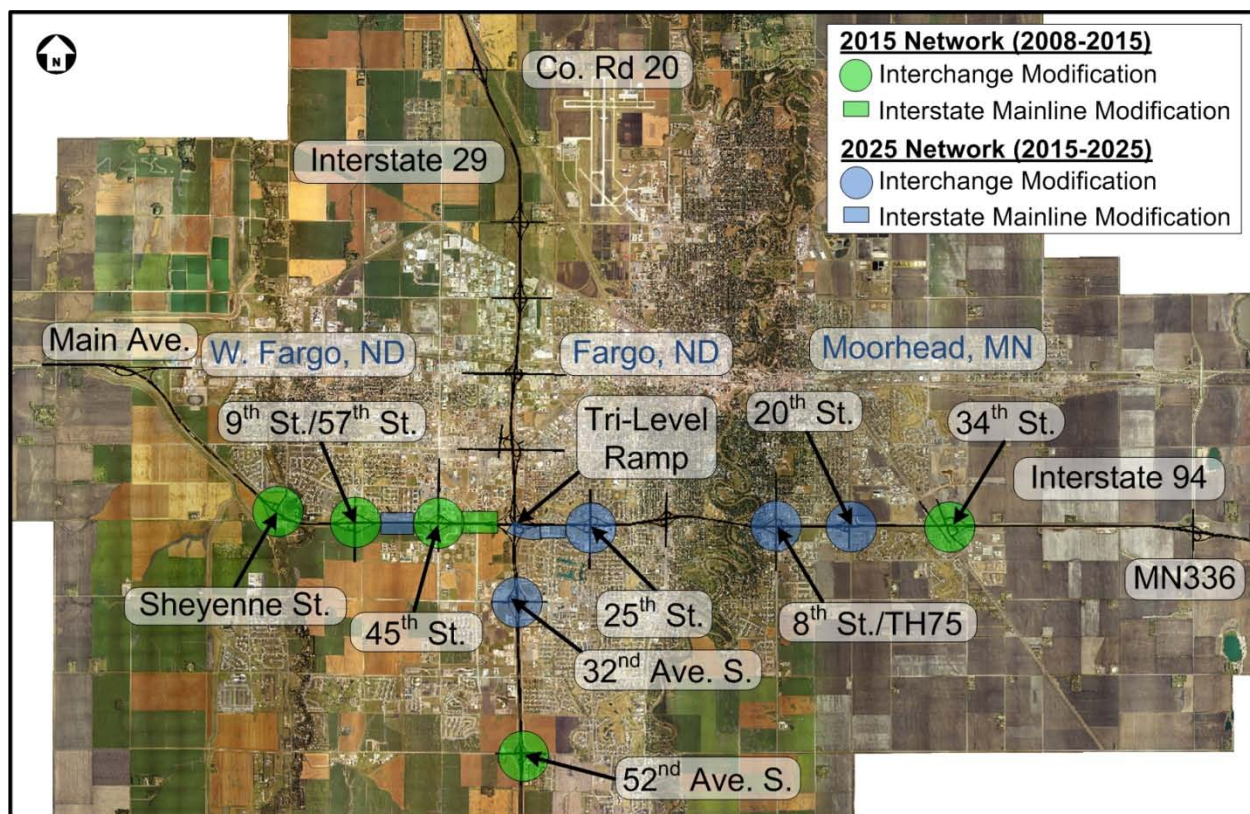

Figure 1. 2025 F-M IOS VISSIM network (changes from 2008 and 2015 networks are noted)

2025 NETWORK IMPROVEMENTS

Several interchanges and mainline sections were modified to reflect the proposed 2025 freeway conditions. These modifications were based on discussions among the Steering Committee and represent plausible network improvements. The 2008 and 2015 conditions are documented in Technical Memorandum II and Technical Memorandum III, respectively. Since the I-29 corridor within the metro area was reconstructed from 2001-2007, most of the geometric and traffic control modifications for the 2025 network occur along I-94.

Since this study focuses on evaluating the freeway operations, the details of the signal timing and arterial roadways are not critical to the study. However, these data will be beneficial for future simulation projects within the F-M area. Descriptions and VISSIM screenshots of the modifications from the 2015 network are provided in the following sections.

I-94 between 9th St. and 45th St.

- Updated Geometry: Auxiliary lanes for eastbound (#1) and westbound (#2) directions

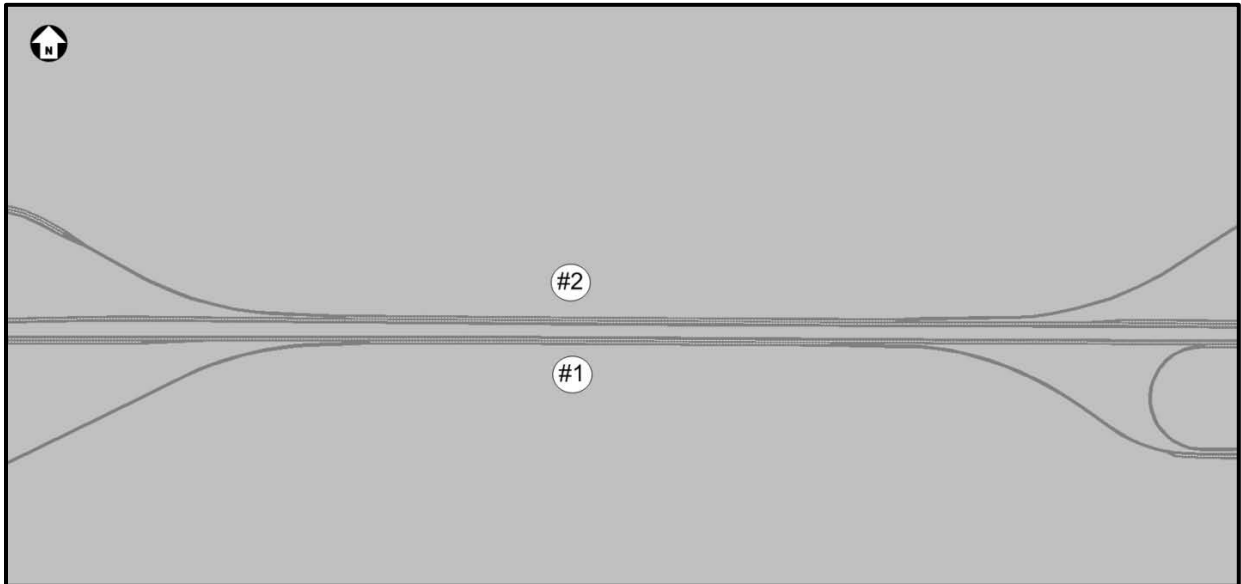

Figure 2. I-94 between 9th St. and 45th St. (2025 VISSIM)

Tri-Level Ramp Merge Area

- Updated Geometry: Two lane tri-level ramp (#1) and eastbound auxiliary lane between I-29 and 25th St. (#2)

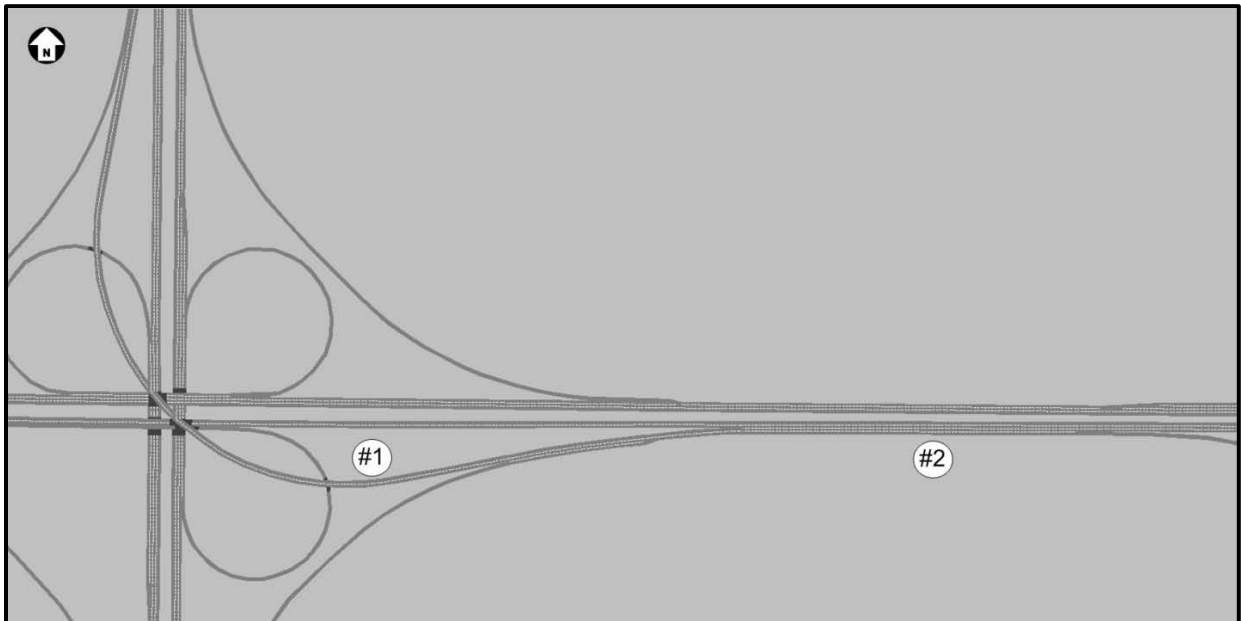

Figure 3. Tri-level merge area with auxiliary lane to 25th St. (2025 VISSIM)

I-94 & 25th St. Interchange (South Ramp)

- Updated/new Geometry: Eastbound on-ramp (#1), westbound/eastbound approaches (#2)
- Updated Traffic Control: Signal phasing/timing (removed northbound left-turn phase)

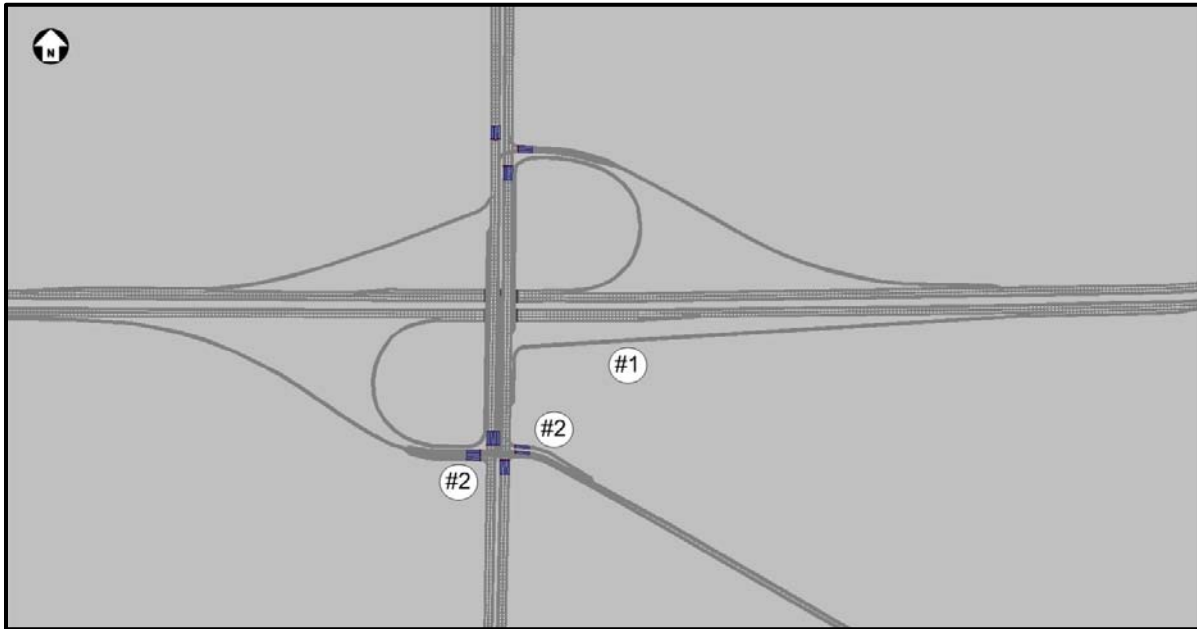

Figure 4. I-94 & 25th St. (2025 VISSIM)

I-94 & 8th St. (TH 75) Interchange

- Updated/new Geometry: Eastbound off-ramp (#1), southeast loop ramp (#2), northeast loop ramp (#3), 8th St. northbound between loop ramps (#4)
- Updated/new Traffic Control: Signal phasing/timing (removed north ramp's northbound left-turn phase)

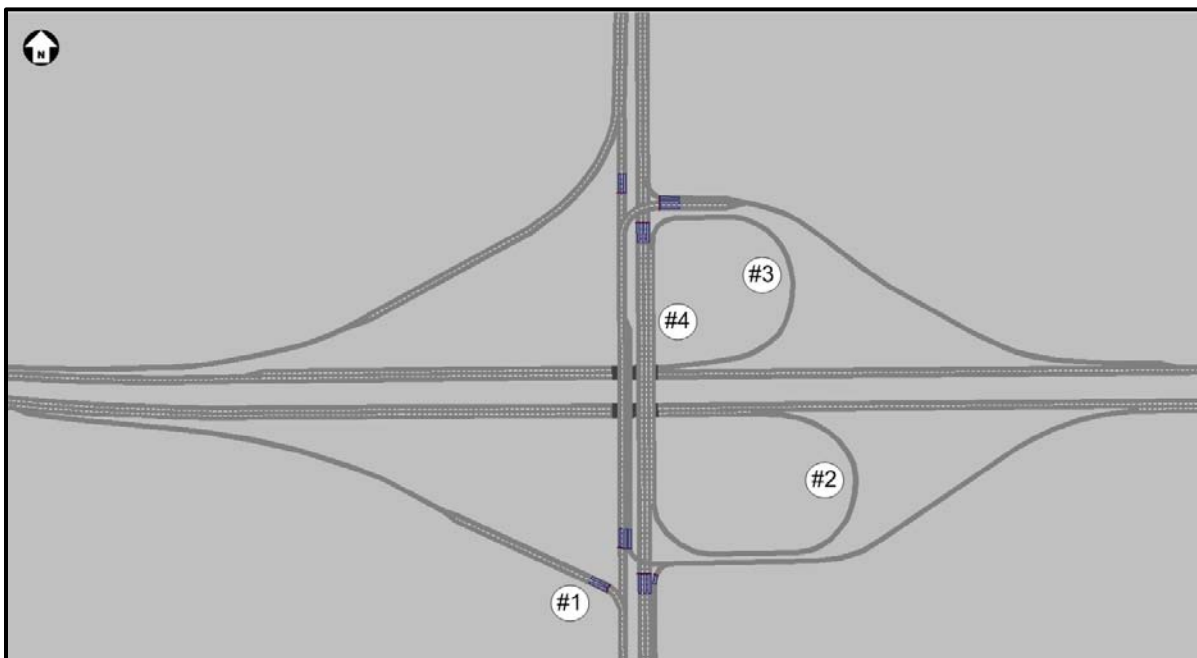

Figure 5. I-94 & 8th St. Interchange (2025 VISSIM)

I-94 and 20th St. Interchange

Updated/New Geometry: southwest loop ramp (#1), westbound off-ramp (#2)

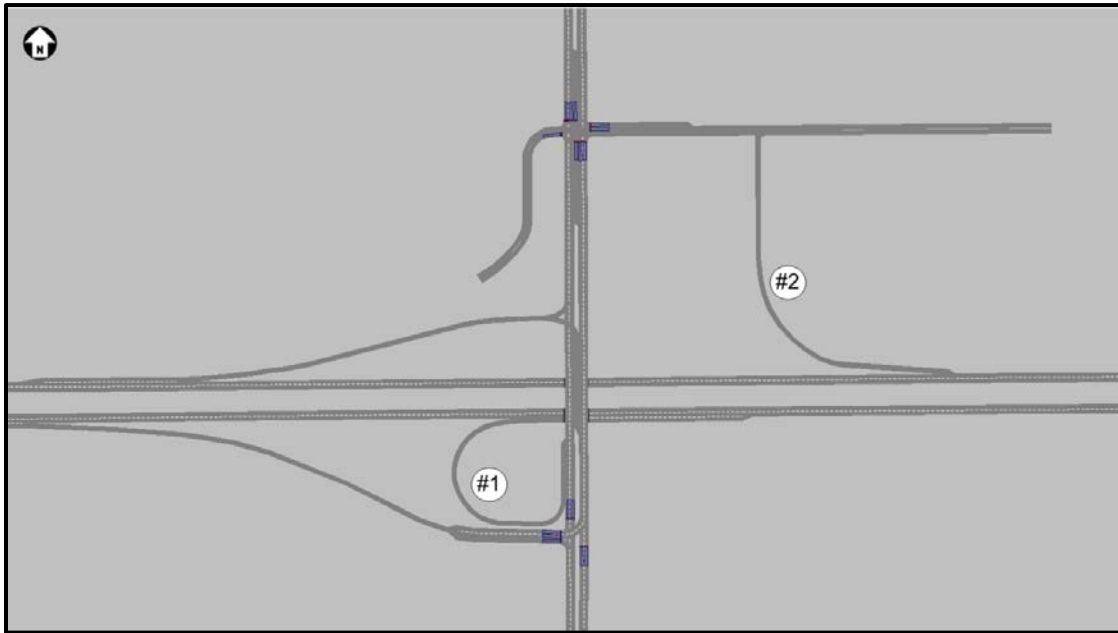

Figure 6. I-94 and 20th St. Interchange (2025 VISSIM)

I-29 and 32nd Ave. S. Interchange

- Updated/New Geometry: Northwest loop ramp (#1), 32nd Ave. S. westbound (#2)
- Updated Traffic Control: Signal phasing/timing (removed west ramp's westbound left-turn phase)

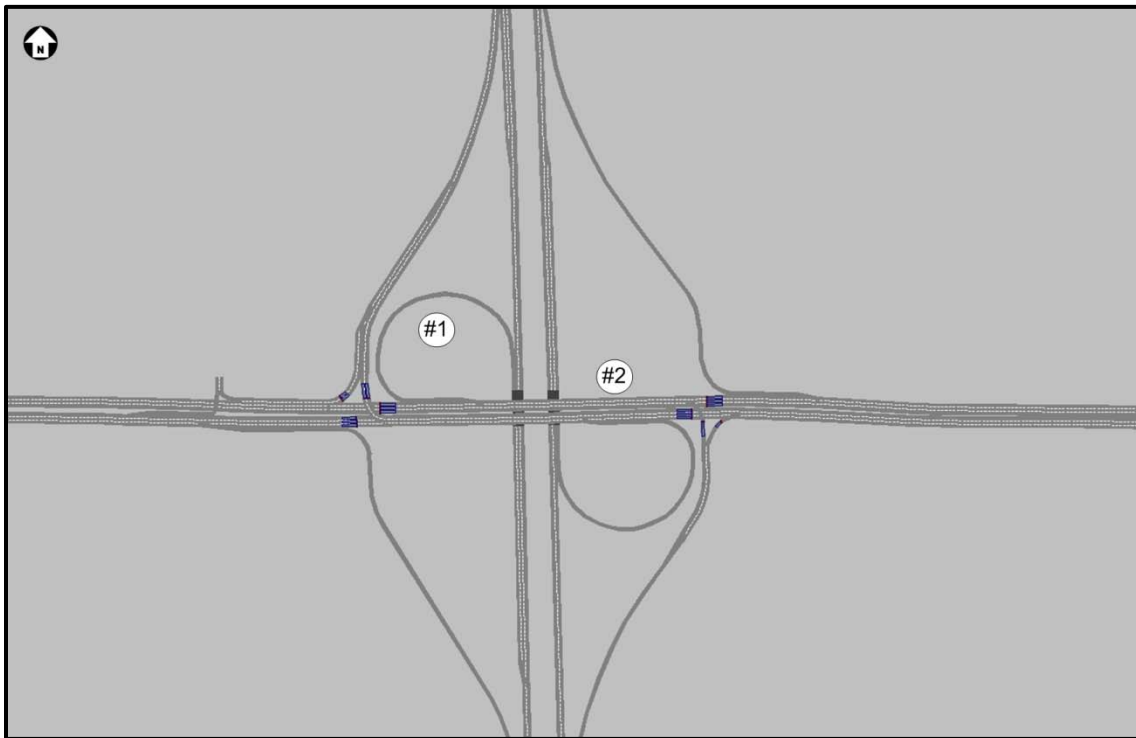

Figure 7. I-29 and 32nd Ave. S. Interchange (2025 VISSIM)

TRAFFIC CONTROL DEVICES

Most of the ramp terminals located within the metro area are controlled by traffic signals. The signal timing data for the 2008 AM and 2008 PM peak periods were used as a basis for the 2025 AM and 2025 PM simulation scenarios. A total of 30 traffic signals were modeled for the 2025 scenarios. Signal timing modifications were made when phases were removed and when ramp congestion developed.

TRAFFIC VOLUME INFORMATION

To account for conservative traffic growth, an average growth rate of 1.75% (simple interest) was used for the 2025 planning horizon (which was also used for the 2015 analyses), providing a 30% increase to the 2008 field counts. The 2025 target volumes were entered into the travel demand model's sub-area networks (Citilabs' Cube software) and Cube's Matrix Estimator (ME) was used to provide new origin-destination (O-D) matrices.

Since several network changes have been introduced since the 2008 network, target values were primarily used at the boundaries of the analysis network and areas that did not have major geometric changes. The targets were incorporated on the mainline sections, as well as the on- and off-ramps. The locations that did not have target values include the following:

- I-94 and Main Ave. Interchange (ramps and mainline sections west of interchange)
- I-94 and Sheyenne St. Interchange (ramps and mainline sections east of interchange)
- I-94 and 9th St. Interchange (ramps and mainline sections east and west of interchange)
- I-94 and 45th St. Interchange (ramps and mainline sections west of interchange)
- I-94 and 20th St. Interchange (ramps)
- I-94 and 34th St. Interchange (ramps)
- I-94 and MN 336 Interchange (ramps and mainline sections east of interchange)
- I-29 and 52nd Ave. S. Interchange (ramps and mainline sections north and south of interchange)
- I-29/I-94 Interchange (northeast, northwest, and southeast loop ramps)

Vehicle Composition

Similar to the 2008 and 2015 simulation scenarios, the 2025 AM and PM scenarios incorporated both passenger car and truck O-D matrices. The traffic composition for both 2015 simulation scenarios consisted of passenger cars (95%), tractor-trailer trucks (3%), and single-unit trucks (2%). These vehicle percentages were applied to the O-D matrices.

Peak Hour Origin-Destination Demand

To account for the variation in traffic demand within the peak periods, the peak-hour O-D matrices were factored at 5-minute intervals. The 2015 simulation scenarios used the same O-D demand factors as their respective 2008 simulation scenario, which were obtained by averaging interval data from 9 freeway mainline locations. The average peak-hour factors (PHFs) for the 2008 AM and 2008 PM peaks were .78 and .87, respectively.

As traffic volume increases, especially as capacity is reached, so does the PHF. A higher PHF more evenly distributes traffic over the peak-hour period. Since the 2025 peak-hour volumes are significantly higher than the 2008 volumes, a PHF of .92 (which is often used for planning purposes) was used for both AM and PM peak periods. The traffic distributions for the 2008, 2015, and 2025 scenarios are shown in Figure 8.

Although the traffic volumes of the 2025 scenarios are higher than those of the 2015 scenarios, it may not be reflected in some of the simulation output. Using a 1.75% annual growth from

2008, the 2025 traffic is approximately 16% higher than the 2015 traffic. However, the 2025 PHFs for the AM and PM peak periods are lower than those of 2008 by 18% and 6%, respectively. Therefore, the effects of increased traffic volume in the 2025 scenarios, primarily in the AM peak, may be diminished because of the higher PHF.

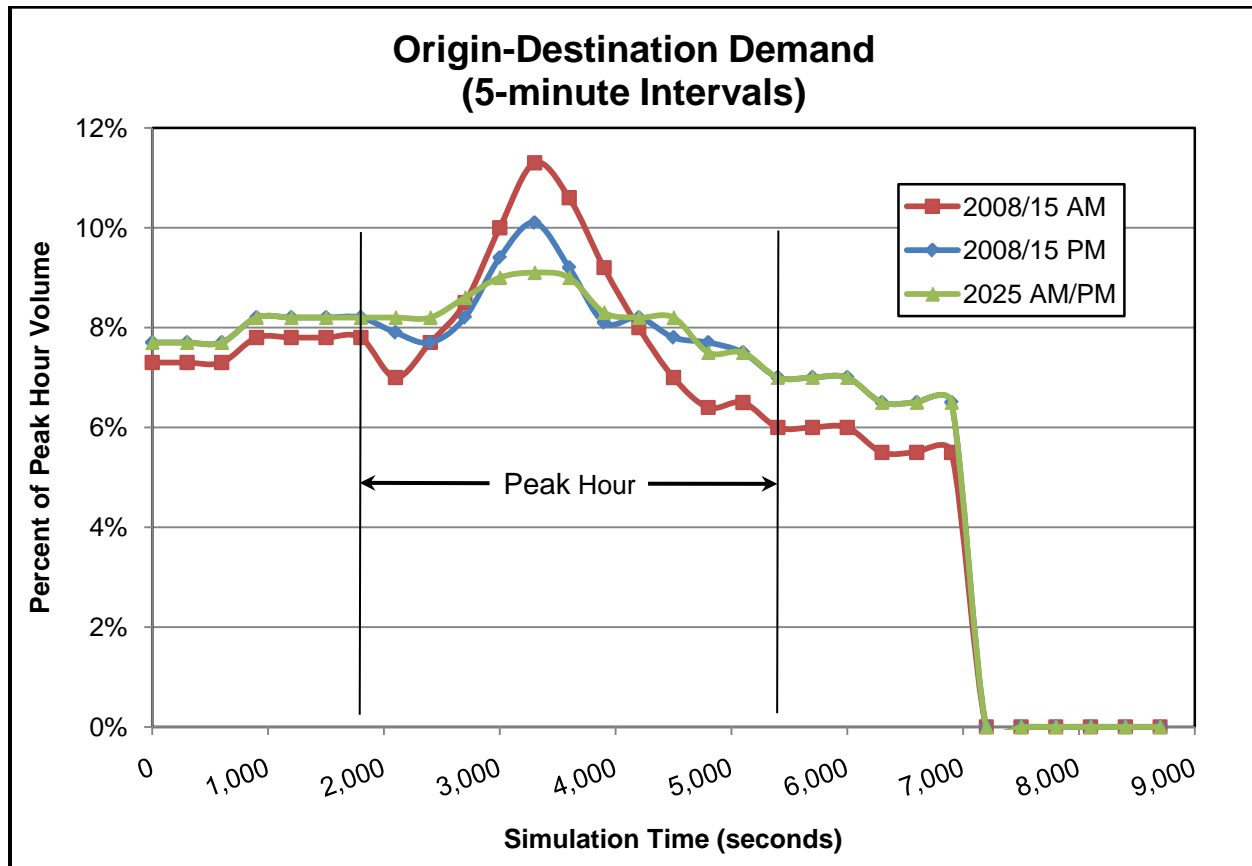

Figure 8. Origin-destination demand for the simulation duration (2008, 2015, and 2025)

SIMULATION DURATION

The simulation duration followed the same timeline as the 2008 and 2015 scenarios. The major components of the two and a half hour simulation are as follows:

- 30-minute off-peak traffic to load traffic into the network
(The numerical output will not be collected during this period)
- 60-minute peak-hour traffic with 12, 5-minute periods
- 30-minute off peak to clear any congestion from the peak-hour period
(The duration of this period may increase based on the severity of congestion)
- 30-minutes of no traffic demand to ensure all vehicles complete their trip

SIMULATION ERROR CHECKING

Since most of the simulation network was already developed, error checking for the 2025 scenario focused on the modifications that were made to the 2015 networks. Similar to the previous scenarios, screen shots of the simulation network were captured and reviewed to ensure all of the network elements were incorporated. In addition, the simulation animation was reviewed, which primarily focused on traffic control and driving behavior.

Error checking also focused on the simulated traffic volume. The simulation output was reviewed to determine if the model was producing the desired traffic based on the O-D matrices.

In addition, PTV AG's VISUM travel demand model was used to read/review the VISSIM O-D paths to ensure that invalid paths did not exist.

SIMULATION CALIBRATION

Calibration is the process of adjusting the simulation model's parameters to reproduce local driver behavior and traffic performance characteristics. The 2008 AM and PM simulation scenarios followed an extensive calibration process (Technical Memorandum II). The process primarily focused on VISSIM's driving behavior, which include car-following and lane-changing models. Both the 2015 and 2025 simulation scenarios incorporated the calibration parameters of the 2008 scenarios.

Due to significant congestion at the I-94 & 8th St. South Ramp during the 2015 PM scenario, two modifications were incorporated into the model. First, the traffic signal plan was adjusted to provide off-ramp traffic with 80 seconds of green time, which doubled the original green time. Second, the driving behavior of the mainline link serving the eastbound off-ramp was changed to allow more realistic lane changing behavior (more aggressive). Otherwise, queues were observed from the 8th St. off-ramp back (upstream) to University Dr. Due to the geometric improvements in the 2025 network, which significantly improved traffic operations, these two modifications were changed back to their original values.

Due to operational issues at the I-94 and 45th St. Interchange during the 2025 PM scenario, the signal timing plan of the north ramp was modified. The westbound off-ramp at the I-94 & 45th St. Interchange during the 2025 PM scenario observed significant queue lengths. This was caused by the significant increase in the westbound left-turn volume for the 2025 PM scenario (976 vehicles), which was more than double the 2008 PM volume (472 vehicles). The large increase in traffic volume was produced since target values were not used in the travel demand model for this interchange. Although the volume exceeded capacity at the off-ramp in the travel demand model, it was favored rather than traveling to 9th St. (note: the travel demand model minimizes route travel time). However, if significant congestion were to occur at the westbound 45th St. off-ramp in the field, motorists would divert to the 9th St. interchange. To combat the high off-ramp volume in the simulation model, the green time of the westbound off-ramp was changed from 40 seconds to 60 seconds.

2025 VISSIM RESULTS

Similar to the 2008 and 2015 scenarios, several measures of effectiveness (MOE) were extracted from the 2025 simulation scenarios. The 2025 AM output is provided in Appendices A through C while the 2025 PM output is provided in Appendices D through F. The values reported for each MOE are averaged from the 30 runs. The project team identified several measures and locations which are summarized as follows:

- Overall Network - vehicle trips, travel time, delay time, etc.
- Interchange Ramps - turning movement volume, delay time, queue length, etc.
- Routes/Locations - vehicle trips, travel time, speed, etc.

Since the O-D matrices and link target values were significantly different among the 2008, 2015, and 2025 scenarios, direct comparisons related to the overall network and interchange node data should not be performed. In addition, the speed limit changes made to portions of I-94 and I-29 for both the 2015 and 2025 networks will affect the travel time output for the pass-through trips (note Technical Memorandum III). However, comparisons related to freeway queue lengths and mainline data collection (especially those with target values) will be performed in this report.

2025 AM Results

Freeway queue length was measured at the tri-level merge area and the westbound I-94 section between 45th St. and I-29 because these two freeway locations experienced congestion during the 2008 PM scenario. Similar to the 2008 AM and 2015 AM scenarios, the 2025 AM scenario does not experience congestion at these locations (Table 1). Modifying the tri-level ramp to two lanes for the 2025 network essentially eliminated queues from occurring during the AM peak period. To improve traffic operations for I-94 westbound traffic between I-29 and 45th St., an auxiliary lane will be constructed in 2010. Benefits were realized for both the 2015 AM and 2025 AM scenarios.

Table 1. Freeway Queue Measurement Locations for AM Peak Hour (2008, 2015, and 2025)

| Simulation Scenario | Tri-Level Merge | | | I-94 WB (45th St) | | |
|---------------------|-----------------|-----------|-------|-------------------|-----------|-------|
| | Avg. (ft) | Max. (ft) | Stops | Avg. (ft) | Max. (ft) | Stops |
| 2008 AM | 0 | 98 | 1 | 0 | 31 | 1 |
| 2015 AM | 1 | 174 | 3 | 0 | 0 | 0 |
| 2025 AM | 0 | 15 | 0 | 0 | 0 | 0 |

The freeway mainline densities of the 2025 AM scenario were comparable to those of the 2015 AM scenario (Table 2). Density values for I-94 and I-29 ranged from 3 pc/mi/ln to 35 pc/mi/ln and 5 pc/mi/ln to 26 pc/mi/ln, respectively. The highest density values were along the westbound sections of I-94 from 20th St. to I-29, which exhibited densities between 29 pc/mi/ln to 35 pc/mi/ln (LOS D-E).

It should be noted that the westbound section of I-94 between 25th St. and I-29 developed congestion during the AM peak period. Since approximately 1,800 vehicles used the I-29/I-94 northeast ramp (westbound to northbound), westbound traffic from the northwest on-ramp and northeast loop ramp of the I-94 and 25th St. Interchange occasionally had difficulty merging onto I-94. While the simulation animation shows periods of congestion, it was not significant enough to lower the average speed of the section, which would produce a higher density value.

Table 2. Freeway Mainline Density for AM Peak Hour (2008, 2015, and 2025)

| I-29 Freeway Mainline | Northbound (pc/mi/ln) | | | Southbound (pc/mi/ln) | | |
|--------------------------------|-----------------------|------|------|-----------------------|------|------|
| | 2008 | 2015 | 2025 | 2008 | 2015 | 2025 |
| CR 20 - 19th Ave. N | 4 | 5 | 5 | 8 | 9 | 9 |
| 19th Ave. N - 12th Ave. N | 9 | 10 | 10 | 10 | 11 | 11 |
| 12th Ave. N - Main Ave. | 18 | 20 | 20 | 11 | 12 | 12 |
| Main Ave. - 13th Ave. S | 24 | 27 | 26 | 13 | 14 | 13 |
| 13th Ave. S - I-94 | 23 | 26 | 25 | 10 | 11 | 10 |
| I-94 - 32nd Ave. S | 19 | 22 | 21 | 9 | 10 | 9 |
| 32nd Ave. S - 52nd Ave. S | 17 | 21 | 19 | 5 | 12 | 12 |
| I-94 Freeway Mainline | Eastbound (pc/mi/ln) | | | Westbound (pc/mi/ln) | | |
| | 2008 | 2015 | 2025 | 2008 | 2015 | 2025 |
| Main Ave. - Sheyenne St. | 3 | 4 | 3 | 6 | 7 | 7 |
| Sheyenne St. - 9th St/57th St. | 12 | 11 | 9 | 9 | 10 | 8 |

| 34th St. - MN 336 | 4 | 6 | 5 | 15 | 17 | 16 |

Note: The yellow highlighted sections represent a LOS D, orange sections represent a LOS E.

Density values at the I-29 & I-94 Interchange were comparable between the 2015 AM and 2025 AM scenarios. The northeast ramp had a high density value (38 pc/mi/ln) since it served the most vehicles (1,801) during the AM peak period (Figure 9). The southeast loop ramp reported a high density (46 pc/mi/ln) since it served 999 vehicles and had a low speed due to the geometric design of the loop ramp. When viewing the simulation's animation, significant congestion was not observed on the ramps. However, congestion would develop occasionally on the westbound weaving segment accessing the northeast ramp.

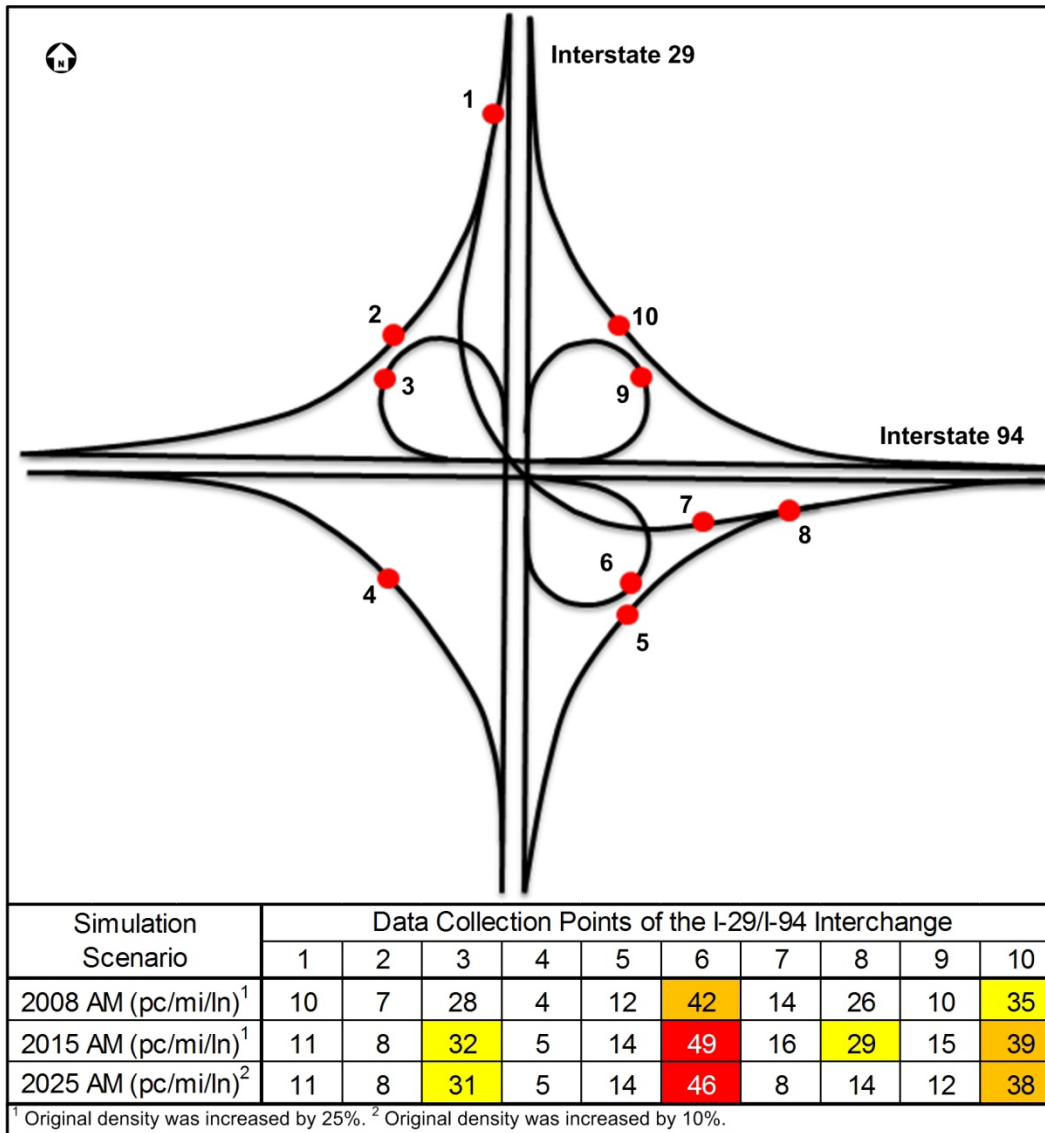

Figure 9. I-29 & I-94 Interchange Density Values (2008 AM, 2015 AM, and 2025 AM)
 Note: LOS D (Yellow), LOS E (Orange), LOS F (Red) – Weaving Segment Methodology

During the 2008 AM scenario, some ramp terminals experienced congestion for at least one movement/approach. The 2015 network implemented several geometric and traffic control modifications to improve traffic operations. These modifications reduced congestion, which developed during the 2008 AM scenario, at the following ramp terminals:

- I-94 & Sheyenne St. North Ramp: Improved due to new traffic control and 9th St./57th St. interchange
- I-94 & Sheyenne St. South Ramp: southbound left-turn movement improved due to new traffic control and 9th St./57th St. interchange. Northbound approach incurs more delay due to signal installation.

The 2025 AM output shows that the 2015 network modifications to the I-94 and Sheyenne St. Interchange provide improved traffic flow compared to the 2008 AM scenario. The congestion is reduced due to the modified traffic control (incorporating traffic signals) at the I-94 and Sheyenne St. Interchange and the construction of the I-94 and 9th St. Interchange.

Due to traffic congestion that occurred at the I-94 & 8th St. (TH 75) Interchange during the 2008 and 2015 scenarios, the 2025 network included a modified interchange. During the AM peak period, a significant amount of traffic travels westbound from the north ramp and significant queues develop for the northbound left-turn movement and the southbound right-turn movements. The modified north ramp eliminated the queues for southbound right-turn and northbound right-turn (which was previously a northbound left-turn) movements (Figure 10). During portions of the 2025 AM simulation, some congestion developed at the merge area from the northeast loop ramp since both the mainline and ramp volumes are significant.

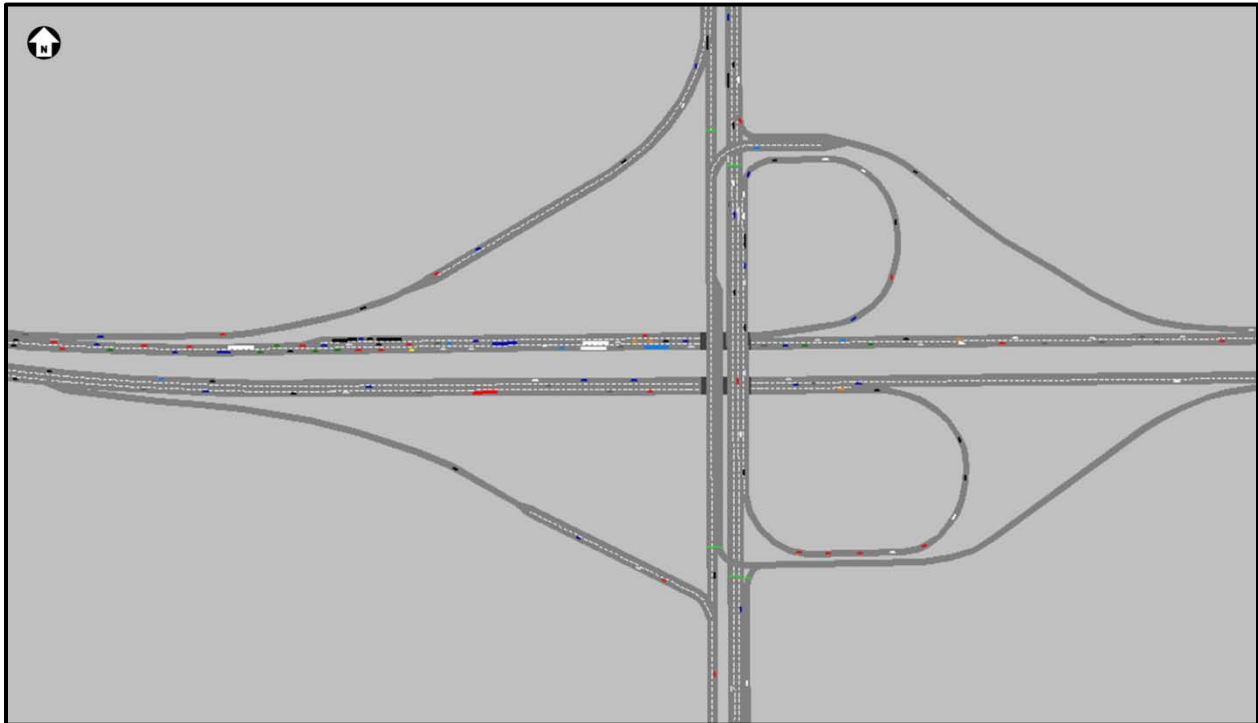

Figure 10. I-94 & 8th St. (TH 75) VISSIM screen shot – 2025 AM peak hour

2025 PM Results

As previously discussed, queue length measurements were collected at the tri-level merge area and westbound I-94 weaving section between 45th St. and I-29 based on congestion experienced during the 2008 PM peak-hour period. During both the 2008 PM and the 2015 PM scenarios, the tri-level merge area experienced significant congestion that produced maximum queue lengths of 2,027 ft and 5,506 ft, respectively (Table 3). To reduce congestion at the merge area, the 2025 network incorporated a two-lane tri-level ramp and auxiliary lane between I-29 and 25th St. These geometric modifications produced a maximum queue length of 361 ft at the merge area. In addition, the westbound auxiliary lane of I-94 between I-29 and 45th St. eliminated queues from developing for both the 2015 PM and 2025 PM scenarios.

Table 3. Freeway Queue Measurement Locations for PM Peak Hour (2008, 2015, and 2025)

| Simulation Scenario | Tri-Level Merge | | | I-94 WB (45th St) | | |
|---------------------|-----------------|-----------|-------|-------------------|-----------|-------|
| | Avg. (ft) | Max. (ft) | Stops | Avg. (ft) | Max. (ft) | Stops |
| 2008 PM | 184 | 2,027 | 454 | 19 | 439 | 49 |
| 2015 PM | 2,323 | 5,506 | 3,201 | 0 | 0 | 0 |
| 2025 PM | 2 | 361 | 10 | 0 | 0 | 0 |

Further analysis was performed into the queue length that developed at the tri-level ramp merge area during the 2025 PM peak period. It was assumed that the geometric modifications in this area would eliminate queues from developing. Upon reviewing the simulation's animation, congestion occasionally develops due to lane changes or weaving after the tri-level ramp/southeast ramp merge area and shortly after the merge with eastbound I-94. Due to the large amount of traffic in this area, a sudden lane change can cause a shockwave to develop upstream. Although the shockwave clears in a rather short period of time and may only occur a few times during the peak hour, the congestion will be reported in VISSIM as a queue. It should also be pointed out that the average speed at the merge area during the peak hour of the 2025 PM scenario was 54 mph compared to 37 mph for the 2015 PM scenario.

An example of this occurrence is shown in Figure 11. A decelerating truck (Veh_1) merging from the southeast ramp onto the tri-level ramp immediately changes lanes into the left lane (it was not exiting at 25th St.), causing a trailing car (Veh_2) to brake. Several other cars in the left lane also had to brake, which created a shockwave of several hundred feet. The shockwave was cleared in less than 25 seconds.

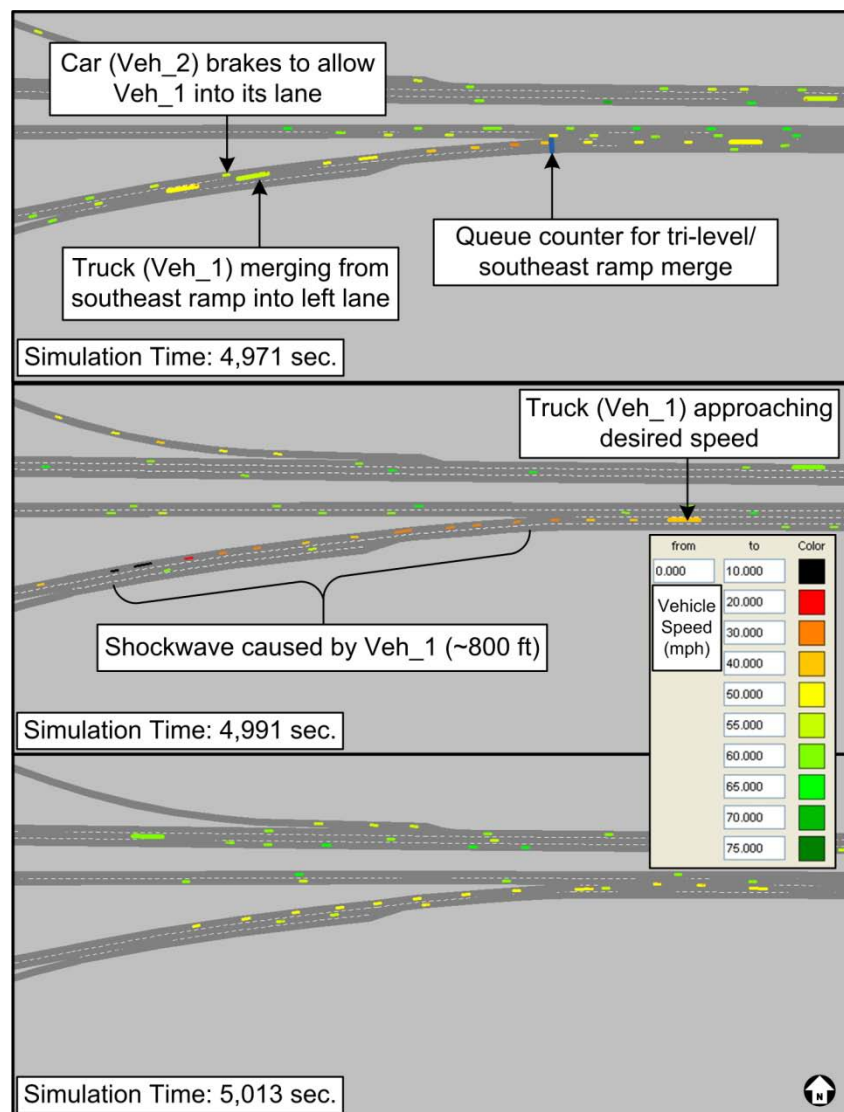

Figure 11. Tri-level ramp merge area VISSIM screen shots - 2025 PM peak hour

The freeway mainline densities of the 2025 PM scenario were comparable to those of the 2015 PM scenario (Table 4). Density values for I-94 and I-29 ranged from 3 pc/mi/ln to 34 pc/mi/ln and 7 pc/mi/ln to 30 pc/mi/ln, respectively. The highest density values were along the eastbound sections of I-94 from 25th St. (Fargo) to 20th St. (Moorhead), having densities ranging from 31 to 34 pc/mi/ln (LOS D).

Table 4. Freeway Mainline Density for PM Peak Hour (2008, 2015, and 2025)

| I-29 Freeway Mainline | Northbound (pc/mi/ln) | | | Southbound (pc/mi/ln) | | |
|--------------------------------|-----------------------|------|------|-----------------------|------|------|

Note: The yellow highlighted sections represent a LOS D.

A few on-ramp merge locations showed signs of periodic congestion during the 2025 PM scenario. Although no quantitative data were collected at these locations, the eastbound on-ramp at 25th St. and the southbound on-ramp at Main Ave. showed some congestion when observing the simulation animation. For both areas, the basic freeway sections between the on-ramp and the next downstream off-ramp are approximately 1,000 ft.

Density values at the I-29 & I-94 Interchange were comparable between the 2015 PM and 2025 PM scenarios except for the tri-level ramp and merge area. The 2025 network improvements to the tri-level ramp (two lanes) and adding an auxiliary lane to 25th St. significantly reduced the density and congestion at the tri-level ramp merge area (Figure 12).

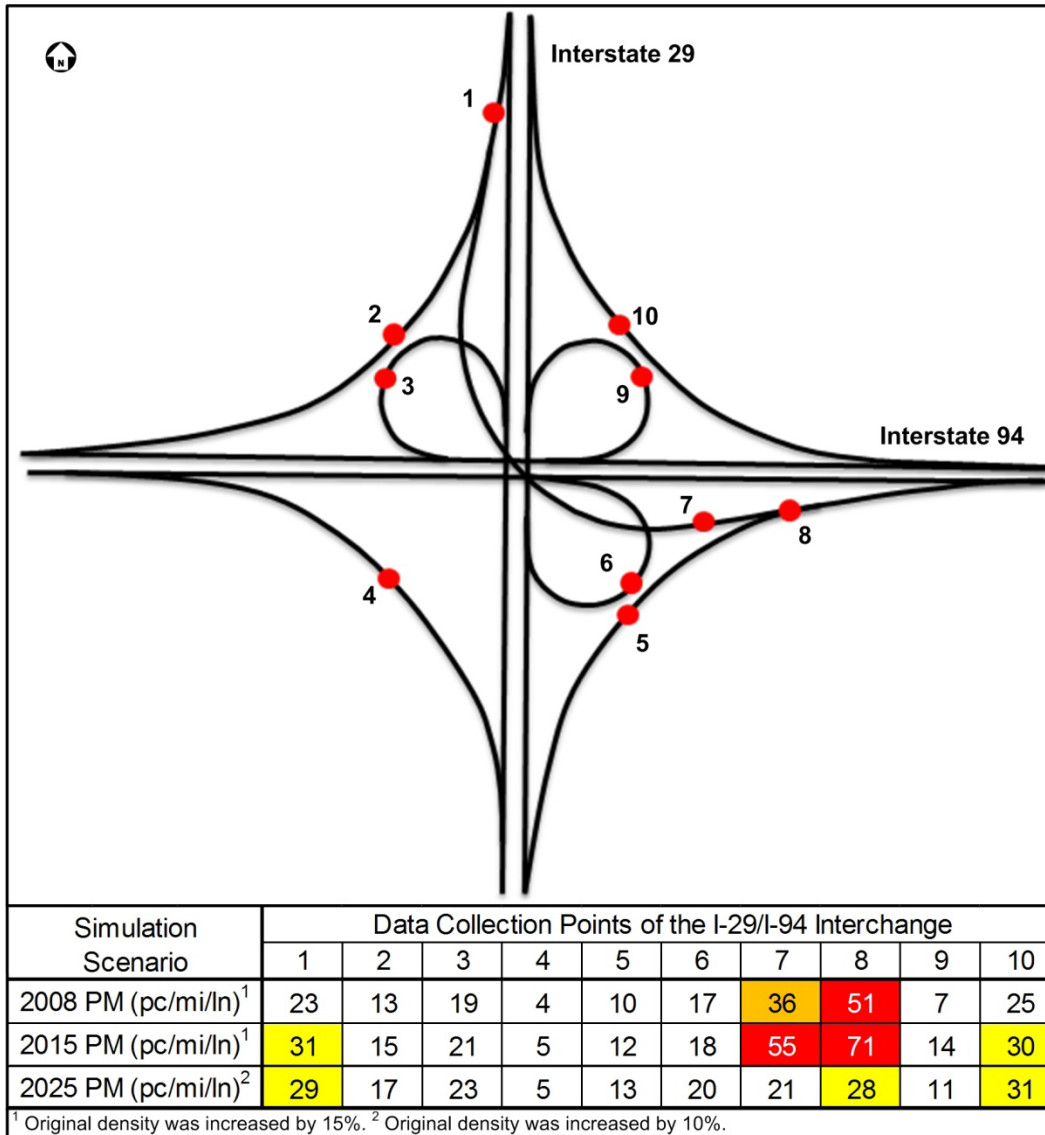

Figure 12. I-29 & I-94 Interchange Density Values (2008 PM, 2015 PM, and 2025 PM)
 Note: LOS D (Yellow), LOS E (Orange), LOS F (Red) – Weaving Segment Methodology

During the 2008 PM scenario, several ramp terminals experienced congestion for at least one movement/approach. Most of these locations were along I-94 between Sheyenne St. and I-29. The 2015 network implemented several geometric and traffic control modifications to improve traffic operations. These modifications reduced congestion, which developed during the 2008 PM scenario, at the following ramp terminals:

- I-94 & Sheyenne St. North Ramp: Improved due to new traffic control and 9th St./57th St. interchange
- I-94 & 45th St. North Ramp: Improved due to modified traffic control and geometry, as well as the 9th St./57th St. interchange
- I-94 & 45th St. South Ramp: Improved due to modified traffic control and geometry, as well as the 9th St./57th St. interchange

Similar to the AM peak hour, the 2025 PM output shows that the 2015 network modifications to the I-94 and Sheyenne St. Interchange improved traffic flow compared to the 2008 PM scenario.

The congestion is reduced due to the modified traffic control at the I-94 and Sheyenne St. Interchange and the construction of the I-94 and 9th St. Interchange.

Since the westbound off-ramp of the I-94 and 45th St. North Ramp during the 2025 PM scenario did not have a target value, the Cube ME assigned significantly more traffic for this off-ramp. The 2015 modifications to this interchange, which included the construction of the I-94 and 9th St. Interchange and the 2025 PM signal timing modification, allowed the ramp to operate adequately.

Similar to the 2025 AM scenario, the modified I-94 and 8th St. (TH 75) Interchange provided operational benefits for the 2025 PM scenario. During the PM peak period, a significant amount of traffic travels from Fargo, ND (from the west) and exists at the 8th St. South Ramp. Both the 2008 PM and 2015 PM scenarios experienced significant congestion. During the 2015 PM scenario, queues from the ramp signal often extended back onto the freeway. The modified south ramp eliminated the queues for the eastbound approach, which include the eastbound off-ramp and the southeast loop ramp (Figure 13).

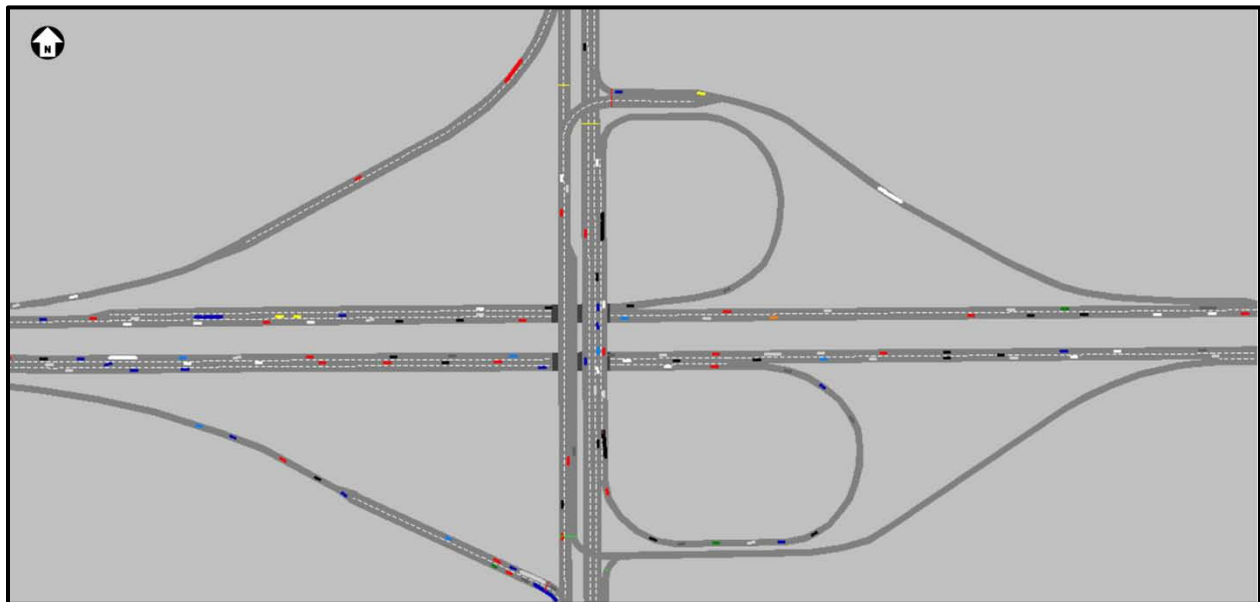

Figure 13. I-94 & 8th St. (TH 75) VISSIM screen shot – 2025 PM peak hour

2025 TRAFFIC WITH 2015 NETWORK (GEOMETRY)

The 2025 AM and PM simulation output illustrated that the proposed network improvements (geometric and traffic control) do a reasonable job of accommodating the estimated 2025 AM and PM peak-hour traffic. Several project stakeholders were interested in illustrating the affects of not continuing with the F-M freeway improvements, which would model the 2025 traffic in the 2015 simulation network (2025/2015). The major geometric improvements for the 2025 network included providing a two lane tri-level ramp with auxiliary lane to 25th St, and reconstructing the I-94 and 8th St. (TH 75) Interchange, which added two loop ramps. Removing these improvements will adversely affect freeway operations; however, this exercise will quantify the congestion. It should be pointed out that severe traffic congestion would alter motorist's route choice to reduce trip travel time.

Although the estimated 2025 traffic will be incorporated, the exact O-D matrices from the 2025 simulation could not be used for these scenarios. This was due to the fact that the I-94 and 20th

St. Interchange of the 2025 network included new geometry (southeast off-ramp and northeast on-ramp), which allows traffic movements not realized in the 2015 network. Most of the trips coming from and going to the east of the interchange were equally split between the I-94 and 8th St. Interchange and the I-94 and 34th St. Interchange. Detailed output of the overall network and freeway mainline results are provided in Appendices G through J. Discussions of simulation results are provided in the following sections.

2025 Traffic/2015 Network AM Output

The freeway mainline densities of the 2025/2015 AM scenario were comparable to those of the 2025 AM scenario. The highest density values were along the westbound sections of I-94 from 20th St. to I-29, which exhibited densities between 30 pc/mi/ln and 36 pc/mi/ln (LOS D-E). Significant congestion occurred at the I-94 and 8th St. Interchange (TH 75), which primarily related to the north ramp's southbound right-turn and northbound left-turn movements (Figure 14).

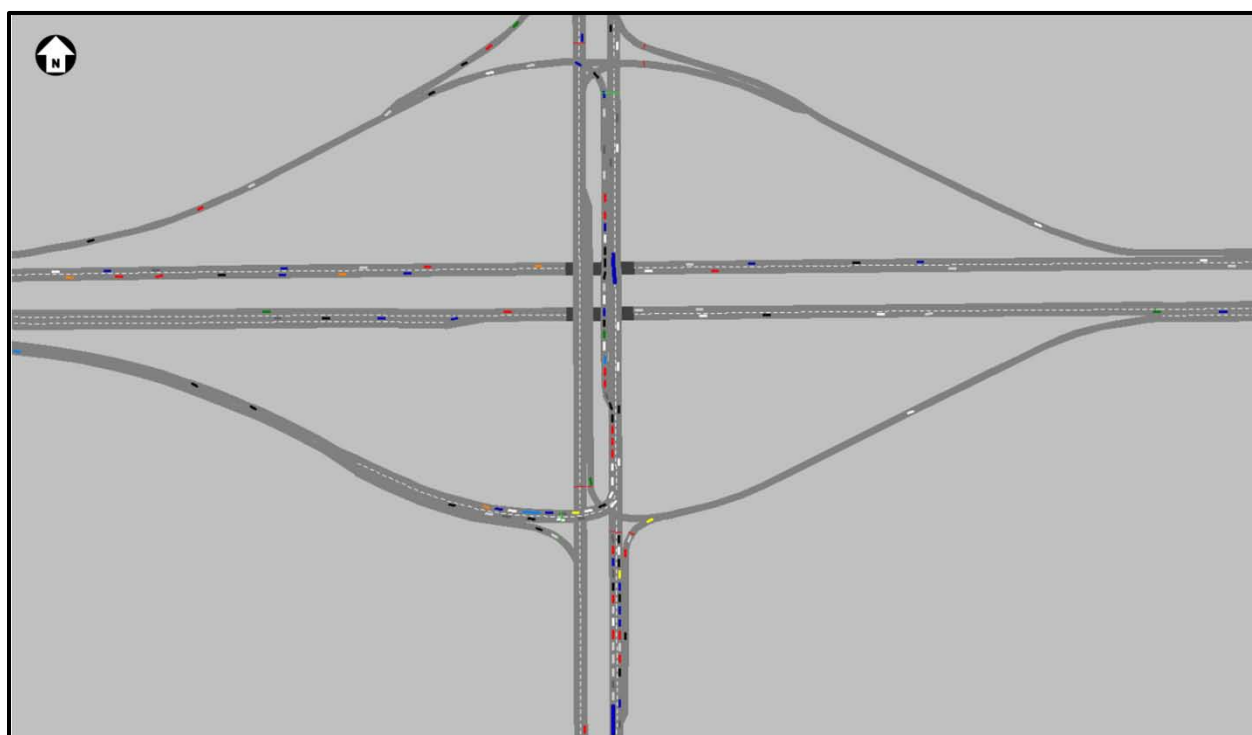

Figure 14. I-94 & 8th St. (TH 75) VISSIM screen shot – 2025/2015 AM peak hour

Comparisons were performed between the 2025 AM and 2025/2015 AM scenarios' delay time. The 2025/2015 AM scenario produced 47% more total delay time and 61% more total stopped delay than the 2025 AM scenario (Table 5). Most of the additional delay can be attributed to the congestion at the I-94 and 8th St. (TH 75) Interchange.

Table 5. Delay Time Comparisons (AM Peak)

| Simulation Scenario | Total Delay Time (hr) | Total Stopped Delay (hr) |
|---------------------|-----------------------|--------------------------|
| 2025 AM | 436 | 142 |
| 2025/2015 AM | 641 | 228 |
| % Difference | 47% | 61% |

To illustrate the difference between the 2025 AM and 2025/2015 AM scenarios, the average link speed for the peak hour was calculated using VISSIM's Link Evaluation feature, which was set up to produce output at 300 ft segments. Figure 15 illustrates the speed comparison between the two scenarios near the I-94 and 8th St. (TH 75) Interchange.

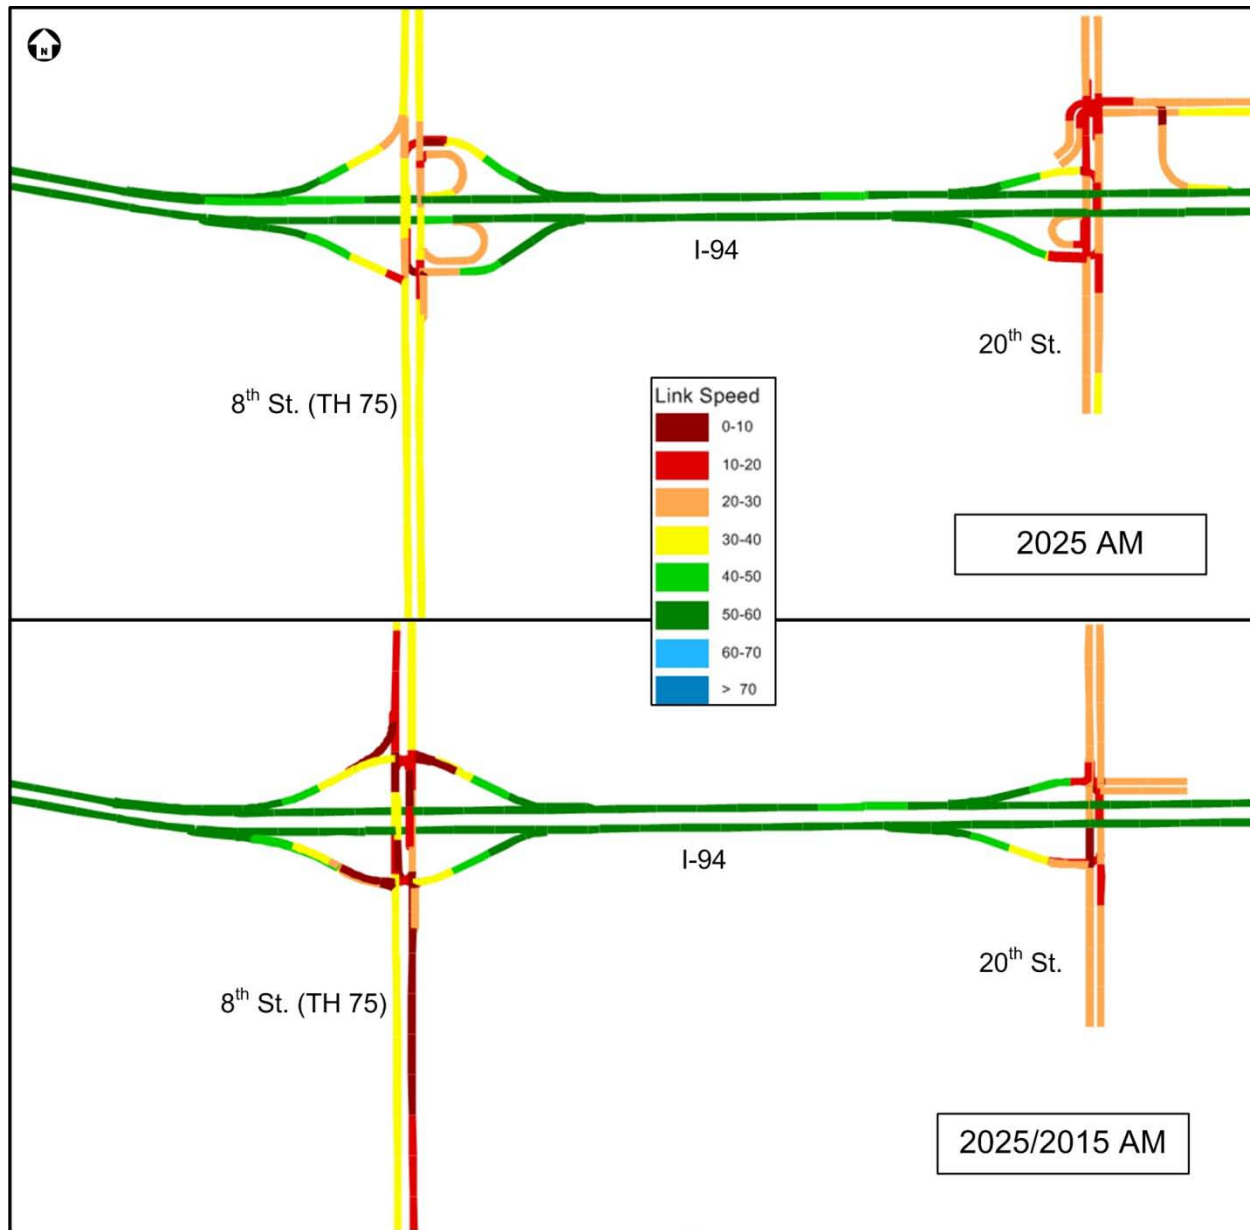

Figure 15. Average link speed – 8th St. (TH 75) and 20th St. (2025 AM and 2025/2015 AM)

2025 Traffic/2015 Network PM Output

The freeway mainline densities of the 2025/2015 PM scenario were higher those of the 2025 PM scenario at several sections. The highest density values were along the southbound sections I-29 between Main Ave. and I-94, which reported densities of 48 pc/mi/ln and 34 pc/mi/ln, respectively (LOS F and D) and along eastbound sections of I-94 from I-29 to 8th St. (TH 75), which exhibited densities between 30 pc/mi/ln to and 42 pc/mi/ln (LOS D-E).

The higher mainline density values for the 2025/2015 PM were a result severe congestion at the tri-level ramp and southeast ramp merge area, as well as at the eastbound off-ramp of the I-94 and 8th St. (TH 75). Since the tri-level ramp has one lane in the 2015 network, the demand for the facility is significantly higher than the capacity (Figure 16). The 2025 PM target volume for the merge area was over 2,600 vehicles; however, only 2,119 vehicles were able to travel through the area using the 2015 network. Therefore, the southbound queue extended to Main Ave.

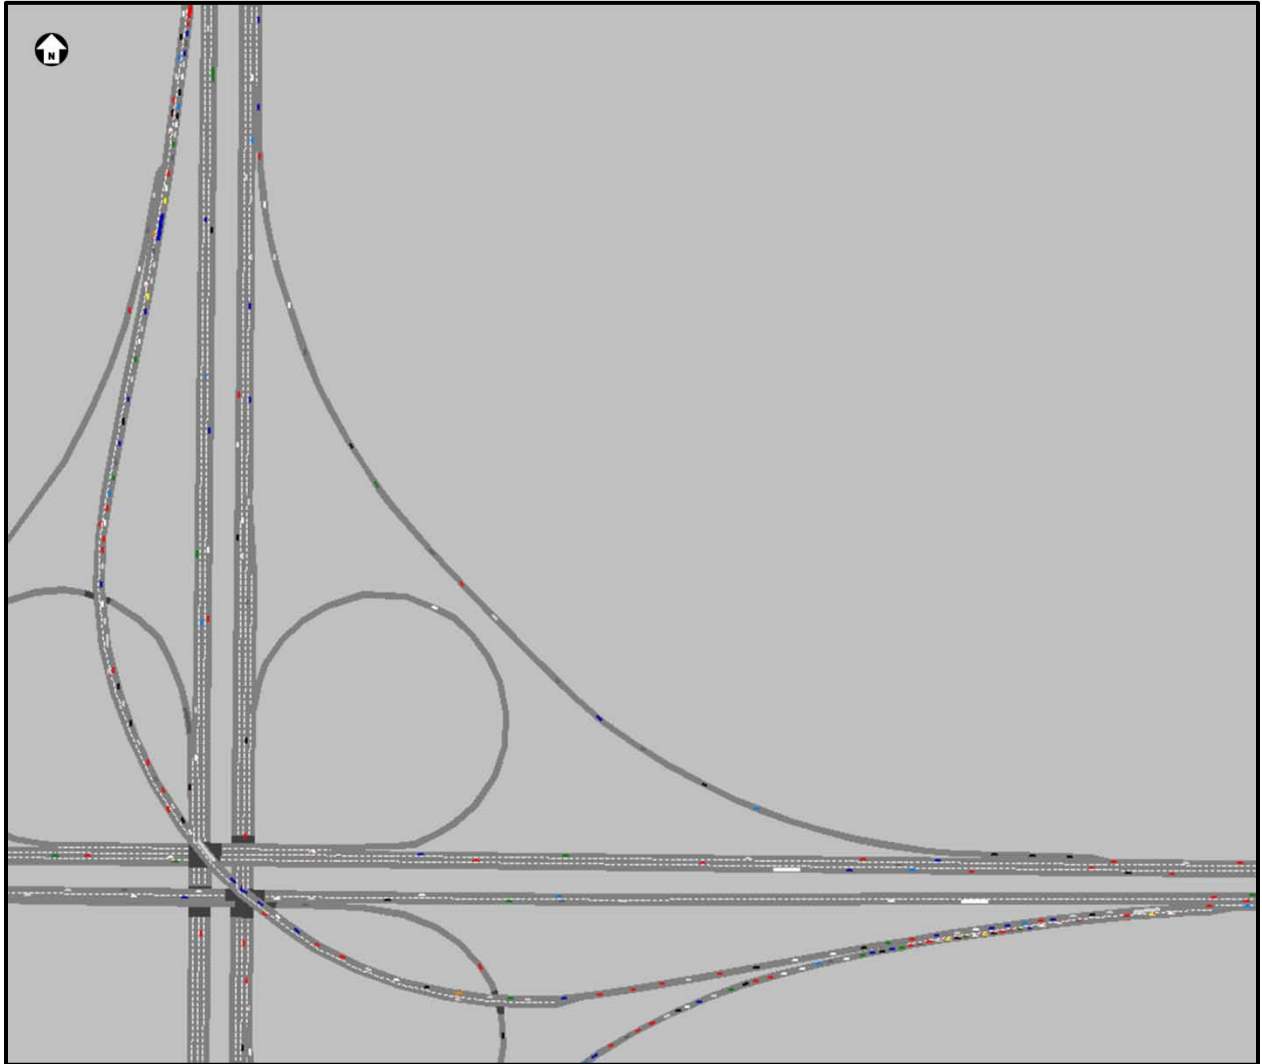

Figure 16. Tri-level ramp merge area VISSIM screen shot – 2025/2015 PM peak hour

Significant congestion also occurred at the I-94 and 8th St. Interchange (TH 75) during the 2025/2015 PM scenario (Figure 17). The eastbound approach of the south ramp queues back onto the eastbound mainline several thousand feet. The proposed 2025 interchange improves traffic operation by separating the eastbound left-turn traffic from the right-turn traffic (southeast loop ramp) and providing two lanes for the eastbound right-turn traffic.

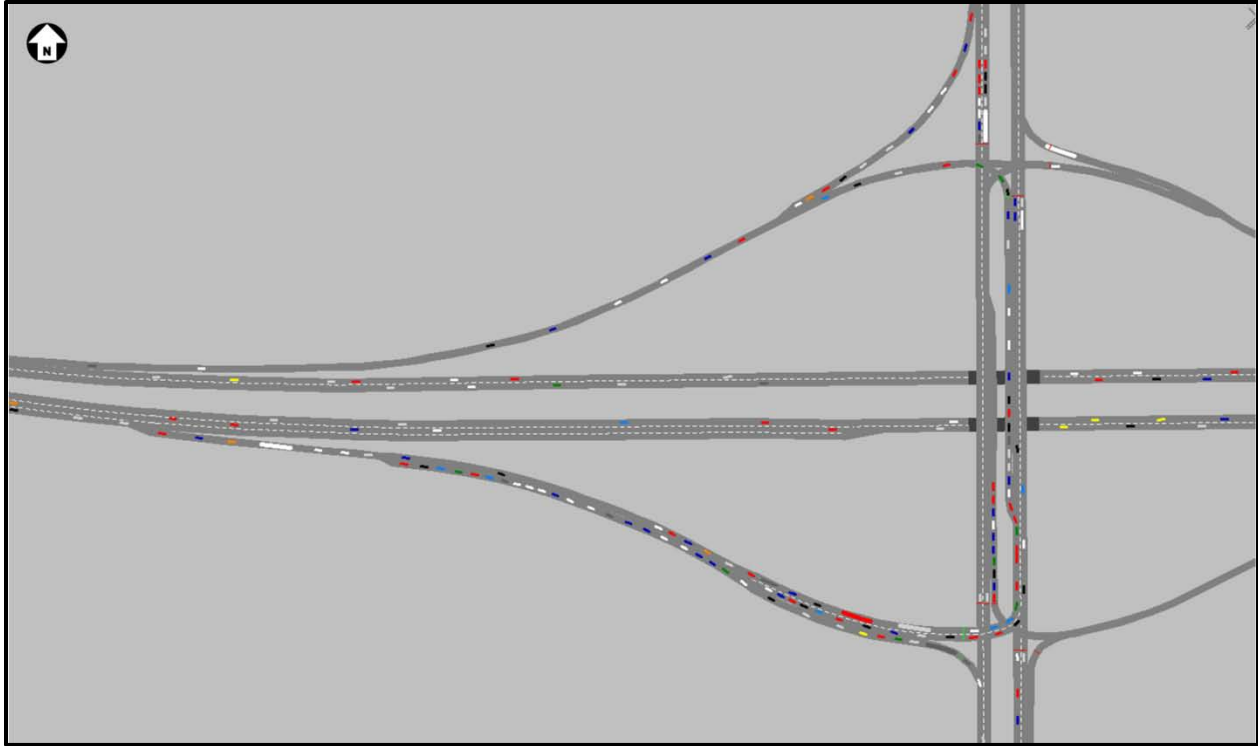

Figure 17. I-94 and 8th St. (TH 75) VISSIM screen shot – 2025/2015 PM peak hour

Comparisons were performed between the 2025 PM and 2025/2015 PM scenarios' delay time. The 2025/2015 PM scenario produced 404% more total delay time and 563% more total stopped delay than the 2025 PM scenario (Table 6). Most of the additional delay was attributed to the congestion at the tri-level ramp and southeast ramp merge area and to a lesser extent the I-94 and 8th St. (TH 75) Interchange.

Table 6. Delay Time Comparisons (PM Peak)

| Simulation Scenario | Total Delay Time (hr) | Total Stopped Delay (hr) |
|---------------------|-----------------------|--------------------------|
| 2025 PM | 473 | 147 |
| 2025/2015 PM | 2,384 | 975 |
| % Difference | 404% | 563% |

To illustrate the difference between the 2025 PM and 2025/2015 PM scenarios, the average link speed for the peak hour was calculated using VISSIM's Link Evaluation feature. Figures 18 and 19 illustrate the speed comparison between the two scenarios near the tri-level ramp and southeast ramp merge area and the I-94 and 8th St. (TH 75) Interchange.

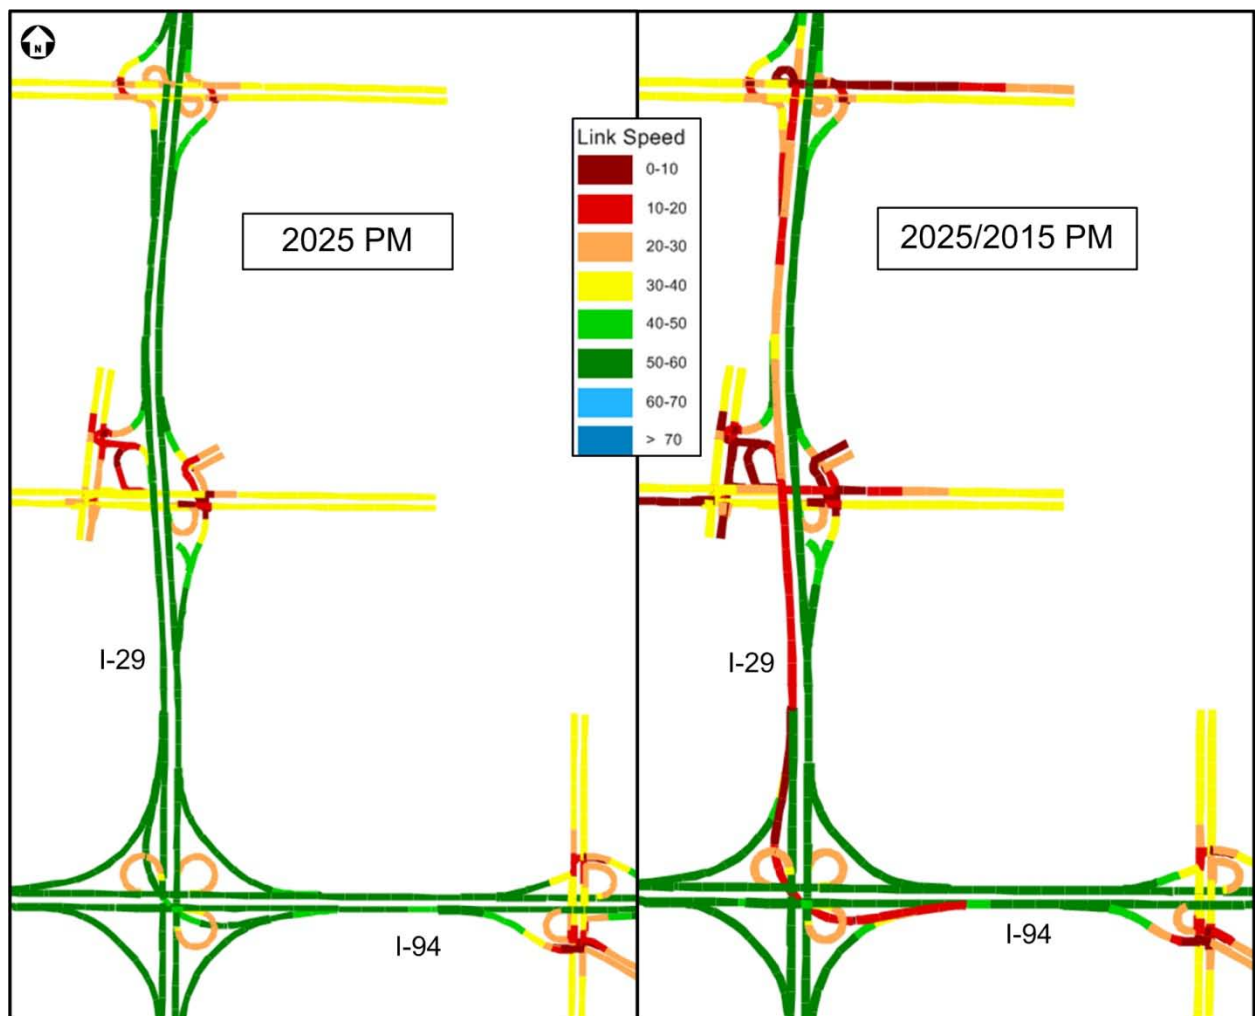

Figure 18. Average link speed – tri-level ramp merge area (2025 PM and 2025/2015 PM)

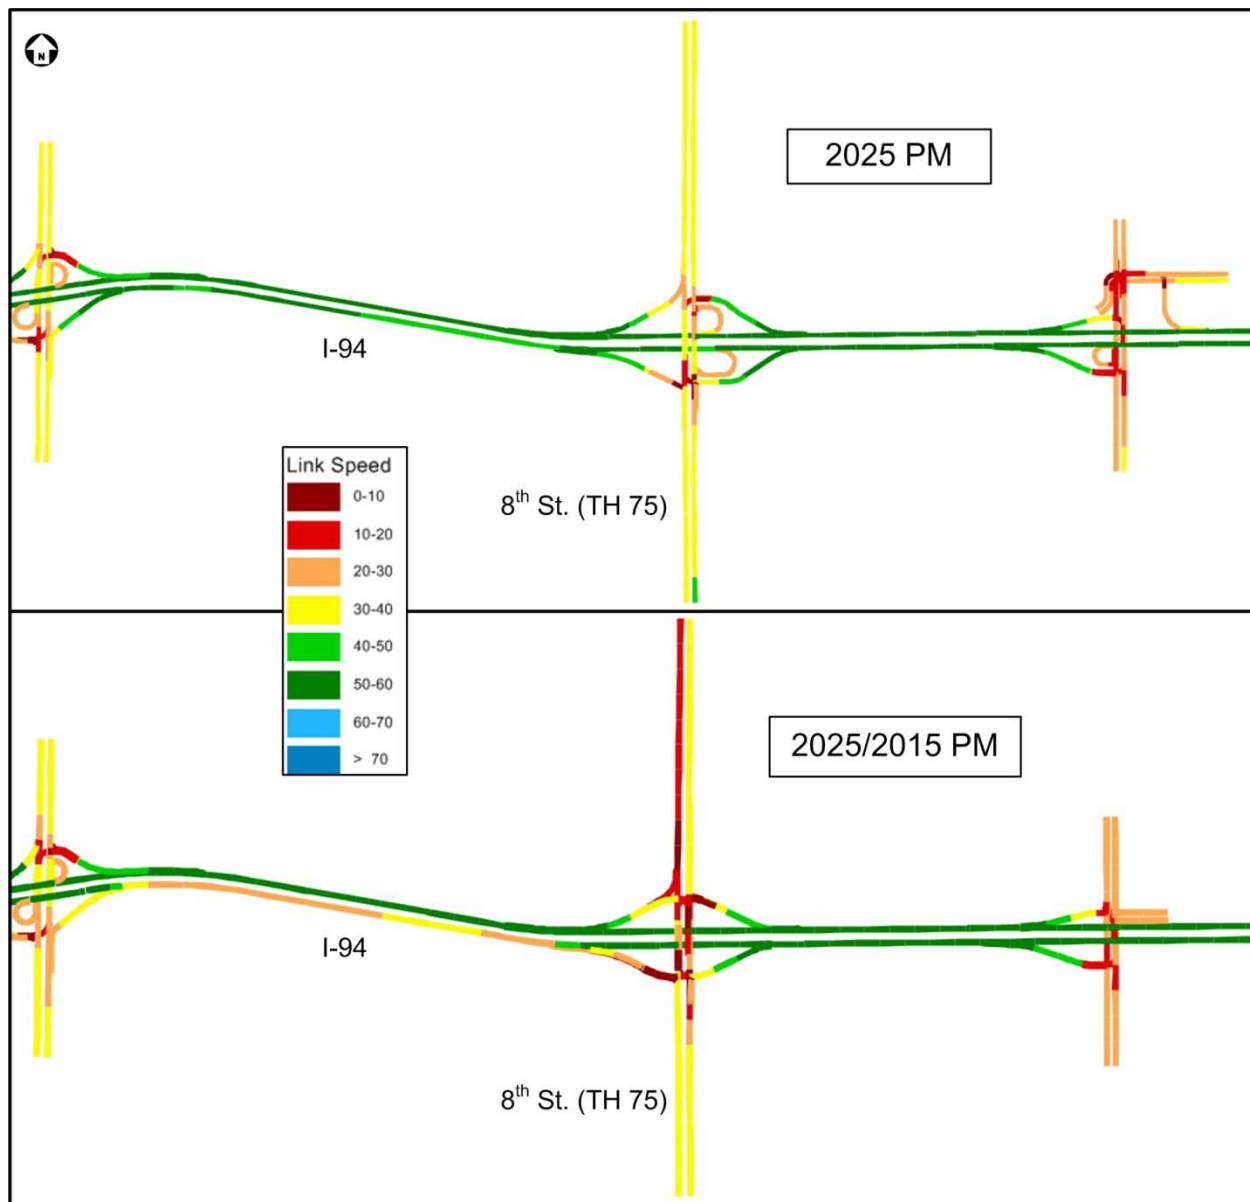

Figure 19. Average link speed – 8th St. (TH 75) (2025 PM and 2025/2015 PM)

SUMMARY

This document provided the simulation results of the 2025 AM and PM scenarios for the Fargo-Moorhead Interstate Operations Study. These scenarios provide insight into the traffic operations issues that may occur in the 2025 planning horizon. Based on the simulation output, the proposed near-term (by 2015) and long-term improvements (by 2025) reduced congestion at several areas within the study area during the peak-hour periods.

The freeway mainline densities of the 2025 AM scenario were comparable to those of the 2015 AM scenario. The highest density values were along the westbound sections of I-94 from 20th St. (Moorhead, MN) to I-29, which exhibited densities between 29 pc/mi/ln to 35 pc/mi/ln (LOS D-E). When viewing the simulation animation, the westbound section of I-94 between 25th St. and I-29 developed some congestion during the AM peak period due to the significant amount of traffic using the northeast ramp of the I-29 & I-94 Interchange.

Mainline density values at the I-29 & I-94 Interchange were comparable to those of the 2015 AM scenario. The northeast ramp had a high density value (38 pc/mi/ln) since it served the most vehicles (1,801) during the AM peak period. The southeast loop ramp reported a high density (46 pc/mi/ln) since it served 999 vehicles and had a low speed due to the geometric design of the loop ramp. When viewing the simulation's animation, significant congestion was not observed on the ramps. However, congestion would develop occasionally on the westbound weaving segment accessing the northeast ramp.

The ramp terminals for the 2025 AM scenario did not experience any significant traffic delay. The addition of the I-94 and 9th St. Interchange reduced congestion at the I-94 and Sheyenne St. Interchange and I-94 and 45th St. Interchange. The most influential improvement to this scenario related to the modified design of the I-94 & 8th St. (TH 75) Interchange, which significantly reduced congestion at the north ramp during the AM peak hour. However, it should be pointed out that some congestion developed at the merge area from the northeast loop ramp since both the westbound mainline and loop ramp volumes are significant.

Modifying the tri-level ramp and merge area (2025 network) alleviated the congestion that developed during the PM peak period. During both the 2008 PM and the 2015 PM scenarios, the merge area significant congestion occurred, producing maximum queue lengths of 2,027 ft and 5,506 ft, respectively. Incorporating a two lane tri-level ramp and auxiliary lane between I-29 and 25th St., eliminated the queues and congestion.

For the 2025 PM scenario, mainline density values for I-94 and I-29 ranged from 3 pc/mi/ln to 34 pc/mi/ln and 7 pc/mi/ln to 30 pc/mi/ln, respectively. The highest density values were along the eastbound sections of I-94 from 25th St. (Fargo) to 20th St. (Moorhead), having densities of ranging from 31 pc/mi/ln and 34 pc/mi/ln (LOS D).

A few on-ramp merge locations showed signs of periodic congestion during the 2025 PM scenario. Although no quantitative data were collected at these locations, the eastbound on-ramp at 25th St. and the southbound on-ramp at Main Ave. showed some congestion when observing the simulation animation.

The ramp terminals for the 2025 PM scenario did not experience any significant traffic delay. The addition of the I-94 and 9th St. Interchange reduced congestion at the I-94 and Sheyenne St. Interchange and I-94 and 45th St. Interchange. The modified design of the I-94 & 8th St. (TH 75) Interchange significantly reduced congestion at the south ramp during the PM peak hour.

The scenarios with the 2015 network with 2025 traffic illustrated the affects of not enhancing the freeway system. During the AM Peak period, significant congestion existed at the I-94 and 8th St. (TH 75) interchange. In addition, maintaining the 2015 network generated an additional 203 hours of delay time, which is an increase of 47% from the 2025 AM scenario. Similar to the AM peak period, the PM peak period produced significant congestion at the I-94 and 8th St. (TH 75). However, the tri-level merge area recorded the most congestion. The 2015 network with 2025 traffic generated an additional 1,911 hours of delay time, which is an increase of 404% from the 2025 PM scenario. Although motorists will select alternative routes to reduce their travel time as freeway congestion developments, the 2025 AM and PM analyses illustrate the importance of the long-term improvements.

Note: Density values were adjusted using the following data:
Peak-hour factor = .92
Heavy vehicle percent = 5
This data increased the original density by 10%.

= Target Growth Percentage of 30%

Appendix E: 2025 PM Simulation Output (Data Collection Points)

I-29 Data Collection: 2025 PM Peak Hour

Note: Density values were adjusted using the following data:

= Target Growth Percentage of 30%

Peak-hour factor = .92

Heavy vehicle percent = 5

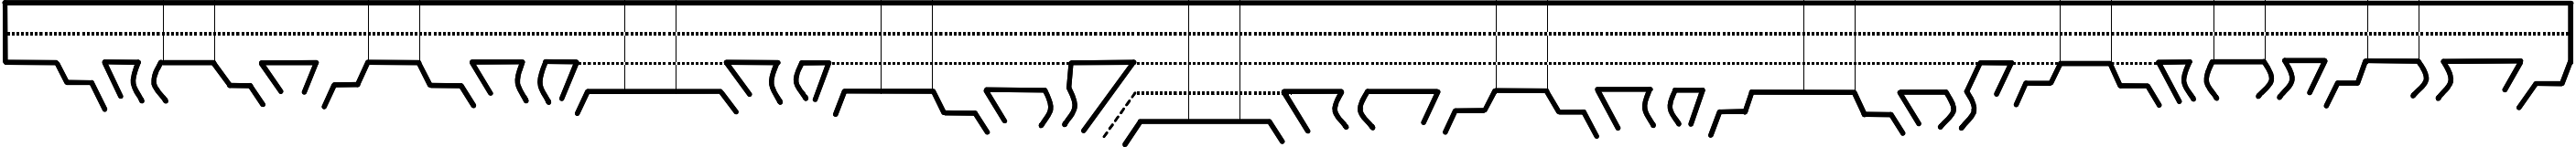

This data increased the original density by 10%.

Appendix H: 2025 AM Traffic with 2015 Network Simulation Output (Data Collection Points)

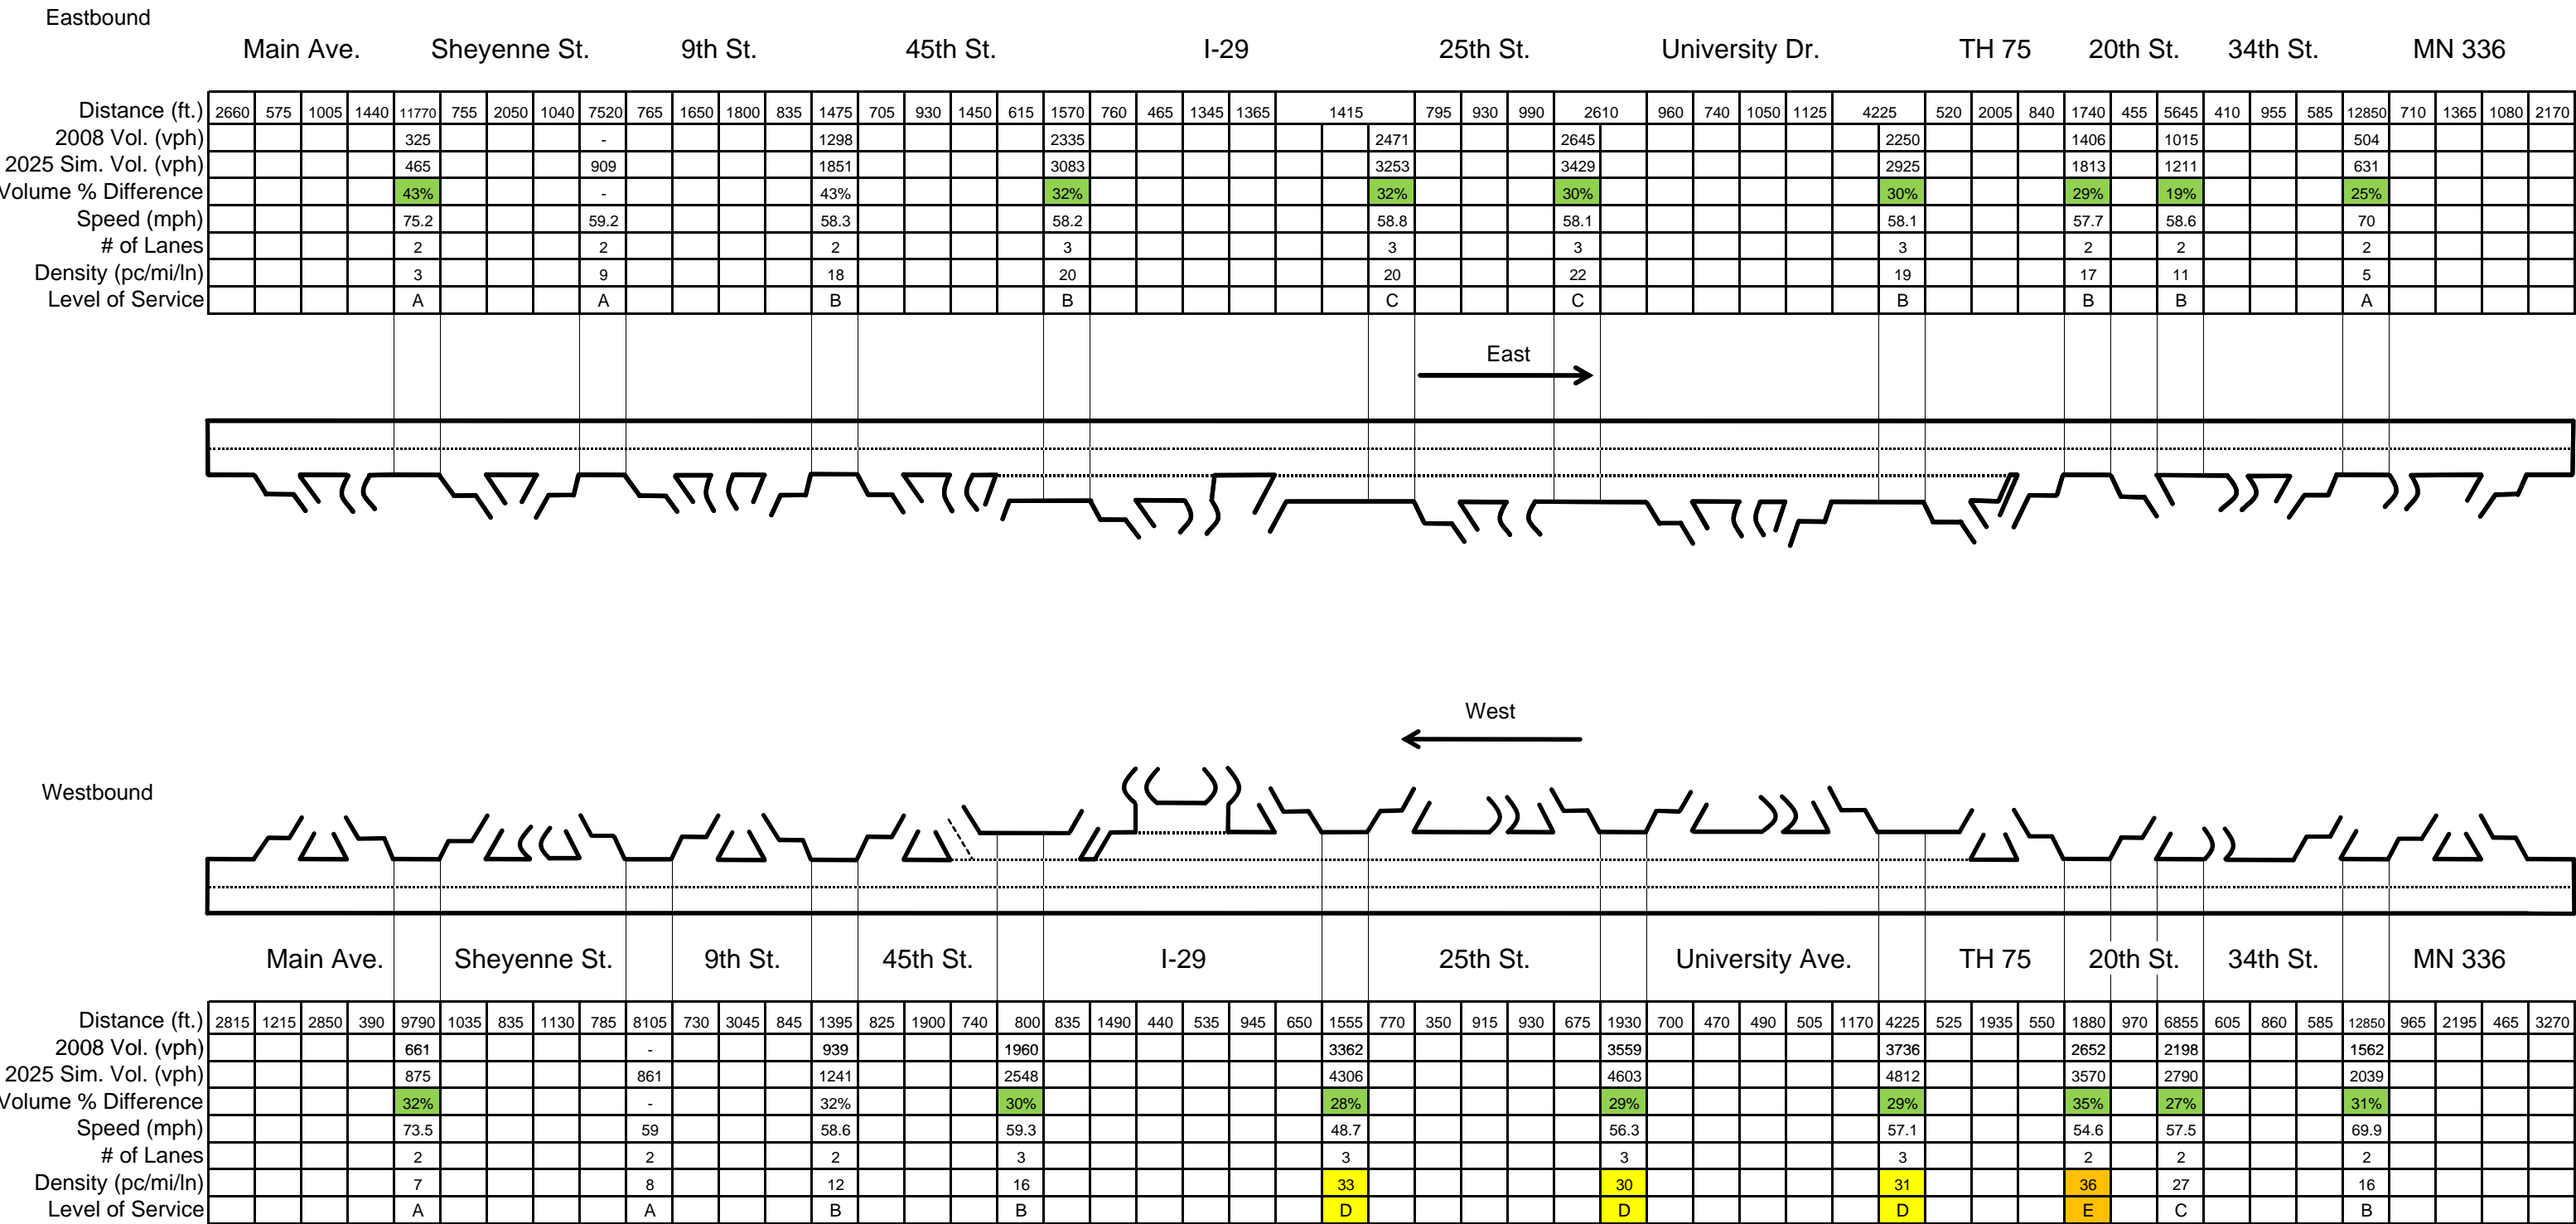

I-29 Data Collection: 2025 Traffic - 2015 Network (AM Peak Hour)

Note: Density values were adjusted using the following data:
Peak-hour factor = .92
Heavy vehicle percent = 5
This data increased the original density by 10%.

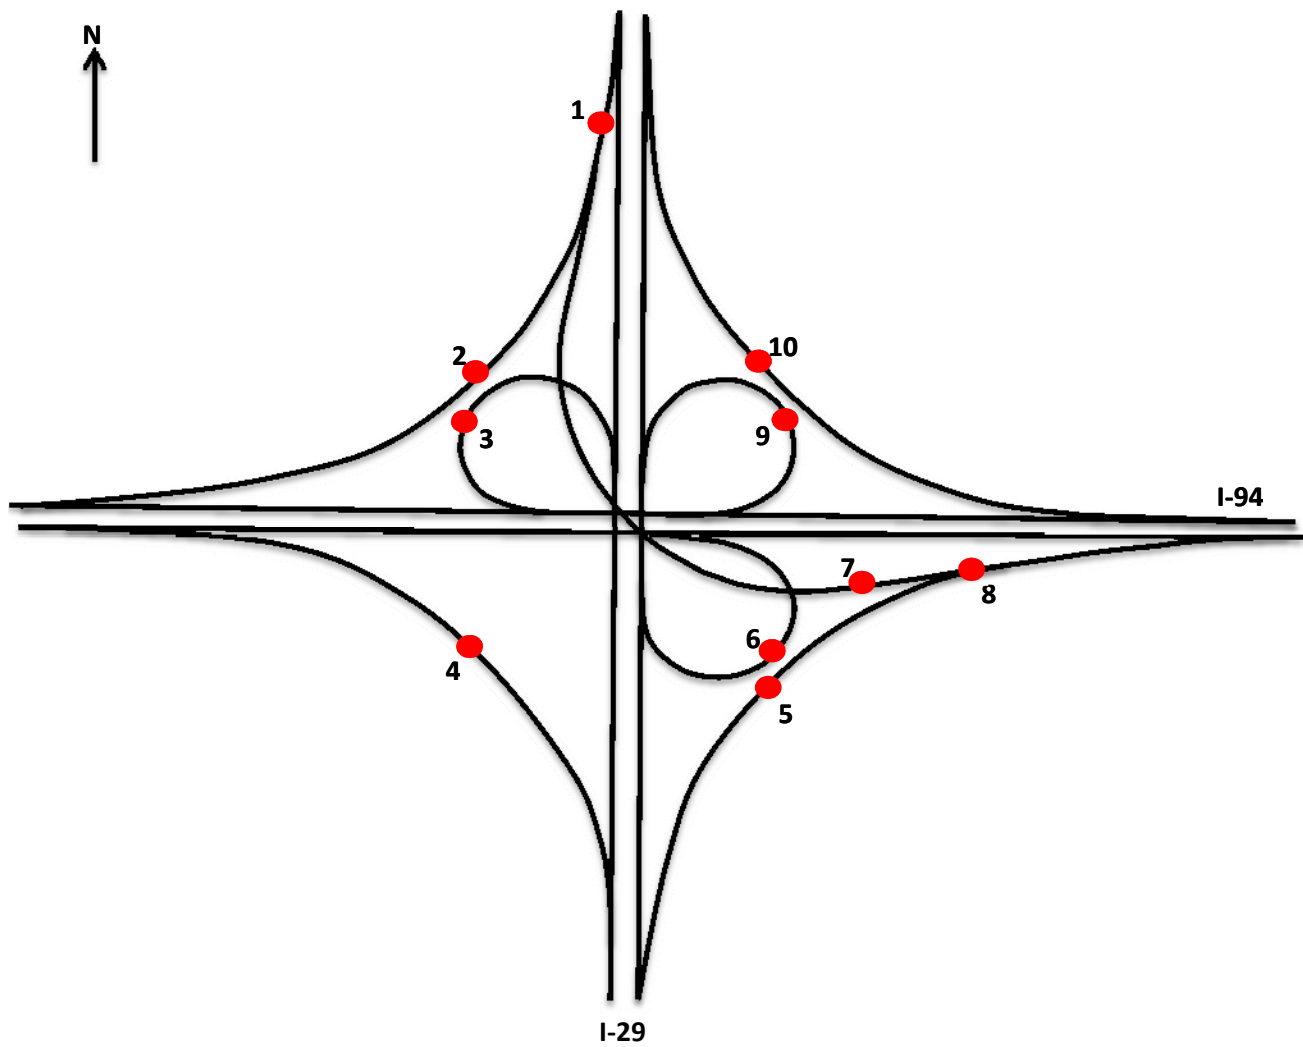

= Target Growth Percentage of 30%

I-94 Data Collection: 2025 Traffic - 2015 Network (AM Peak Hour)

Note: Density values were adjusted using the following data:
Peak-hour factor = .92
Heavy vehicle percent = 5
This data increased the original density by 10%.

= Target Growth Percentage of 30%
